where the concentration of H<sub>2</sub>O is expressed in molecules cm<sup>-3</sup>. If this effect is due to reaction of the hydrated HO<sub>2</sub> complex (i.e. HO<sub>2</sub>•H<sub>2</sub>O + NO → HNO<sub>3</sub> + H<sub>2</sub>O), then the rate constant of the complex with NO is  $\sim 6 \times 10^{-13}$  cm<sup>3</sup> s<sup>-1</sup> at 298 K in the presence of 200 Torr of N<sub>2</sub>.<sup>3</sup>

*Ab initio* electronic structure calculations support the possibility of gas phase HONO<sub>2</sub> formation, but satisfactory simulations using master equations have been elusive.<sup>1,5–7</sup> The measured yields show a surprising intercept at zero pressure, which might be indicative of wall reactions. However, Butkovskaya et al. have made great efforts to minimize wall reactions, and their analysis suggests that wall reactions should not be important.<sup>3,4</sup> Until the results have been confirmed by other groups and are better understood, no recommendation can be made. These rate parameters are provided for the purposes of model evaluation only and do not constitute a recommendation by the Panel.

**C6. HO<sub>2</sub> + NO<sub>2</sub>.** Christensen et al.<sup>2</sup> report rate constants 219 < T/K < 298 and 45 < P/Torr < 200. They show that methanol, present in most other studies confounds the results by forming bound complexes with HO<sub>2</sub>. They also suggest that some measurements yielded low rate constants as a result of perturbations to the NO<sub>2</sub>/N<sub>2</sub>O<sub>4</sub> equilibrium. Sander et al.<sup>8</sup> also noted that H<sub>2</sub>O vapor enhances the reaction rate significantly. Bacak et al.<sup>1</sup> reported data obtained using CIMS, which is more sensitive and less prone to interference than UV and IR absorbance. They used initial radical concentrations 1000 times lower than previous work, eliminating potential interference from the HO<sub>2</sub> + HO<sub>2</sub> reaction. Rate constants measured by Bacak et al.<sup>1</sup> at 200 K, 223 K, and 298 K are quite similar to each other, suggesting very little temperature dependence (i.e., Bacak gives  $n = 0.2$  and  $m = 0.5$ ), which differs from previous work, leading them to conclude that previous work was affected by the HO<sub>2</sub> + HO<sub>2</sub> reaction at T < 277 K. At ~298 K, rate constants measured by Sander et al.,<sup>8</sup> Kurylo et al.,<sup>6,7</sup> Christensen et al., and Bacak et al. are in excellent agreement, suggesting that at 298 K these studies were not affected by interferences. The recommendation is based on the data at T ≥ 277 K from Sander and Peterson,<sup>8</sup> Kurylo and Ouellette,<sup>6,7</sup> Christensen et al.,<sup>2</sup> and the data at 298 K of Bacak et al. The recommended parameters are similar to the previous recommendation; the exponent for  $k_{\infty}$  is small, as expected for a recombination reaction. The low-T data of Bacak et al. fall about a factor of two lower than the fit. Although CIMS experiments have the highest sensitivity and avoid spectral interference, the data are limited to only three temperatures and they have not been replicated at the lowest two temperatures. The error parameter  $g$  was chosen so that the CIMS data at low T fall within the error range. Other studies by Howard,<sup>5</sup> Simonaitis and Heicklen,<sup>9</sup> and Cox and Patrick<sup>4</sup> are in reasonable agreement with the recommendation, as is the value of Christensen et al.<sup>3</sup>

**C7. NO<sub>2</sub> + NO<sub>3</sub>.** The recommended limiting rate constants at 298 K (N<sub>2</sub> bath gas) and temperature exponents are the geometric mean of the corresponding rate constants and the average of the exponents, respectively, obtained by nonlinear least squares. The low pressure limit is based on the data of Kircher et al.,<sup>9</sup> Smith et al.,<sup>12</sup> Wallington et al.,<sup>14</sup> Orlando et al.,<sup>11</sup> and Nakano et al.,<sup>10</sup> combined with k<sub>uni</sub> × K<sub>eq</sub> data (recommended K<sub>eq</sub> from Table 3-1); k<sub>uni</sub> data were taken from Connell et al.<sup>3</sup> and Cantrell et al.<sup>2</sup> The high pressure limit is based on data from Kircher et al.,<sup>9</sup> Smith et al.,<sup>12</sup> Wallington et al.,<sup>14</sup> Hahn et al.,<sup>6</sup> and k<sub>uni</sub> × K<sub>eq</sub> (K<sub>eq</sub> from Table 3-1); k<sub>uni</sub> data were taken from Cantrell et al.<sup>2</sup> and Ide et al.<sup>7</sup> The recommendation is in good agreement with the data of Burrows et al.<sup>1</sup> and with k<sub>uni</sub> (multiplied by K<sub>eq</sub> from Table 3-1) reported by Viggiano et al.<sup>13</sup> Values from Croce de Cobos et al.<sup>4</sup> were excluded due to arguments given by Orlando et al.,<sup>11</sup> who point out that a reanalysis of these data using better values for the rate constant for NO<sub>3</sub> + NO → 2NO<sub>2</sub> yields a negative value for NO<sub>2</sub> + NO<sub>3</sub> + M. The study of Fowles et al.<sup>5</sup> is noted, but not used. Johnston et al.<sup>8</sup> reviewed this reaction. The rate constant for the reverse reaction (k<sub>uni</sub>) can be obtained as the ratio of the recommended recombination rate constant k<sub>rec</sub> from this table, divided by the recommended K<sub>eq</sub> from Table 3-1: k<sub>uni</sub> = k<sub>rec</sub>/K<sub>eq</sub>.

**C8. NO<sub>3</sub> + M.** Johnston et al.<sup>3</sup> and Davidson et al.<sup>1</sup> have suggested significant thermal decomposition of NO<sub>3</sub>. This has been disputed by Russell et al.<sup>4</sup> Davis et al.<sup>2</sup> claim that the barrier to thermal dissociation is 47.3 kcal mol<sup>-1</sup>. This would seem to rule out such a process in the atmosphere.

**D1. HO + CO.** This recommendation takes into account the fact that the reaction proceeds via initial formation of a chemically activated HOCO\* intermediate, which can re-dissociate to HO + CO, dissociate to H + CO<sub>2</sub>, and be collisionally stabilized to yield thermalized HOCO. In the presence of O<sub>2</sub>, the H + CO<sub>2</sub> product set and the HOCO intermediate are both converted to HO<sub>2</sub> + CO<sub>2</sub> (DeMore<sup>6</sup>, Miyoshi et al.<sup>14</sup>). Miyoshi et al. report a rate constant for the reaction HOCO + O<sub>2</sub> → HO<sub>2</sub> + CO<sub>2</sub> of  $\sim 1.5 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  at 298 K (recommended Arrhenius parameters are given in Table 1-1). Therefore, for atmospheric purposes, the products can be taken to be HO<sub>2</sub> and CO<sub>2</sub>. The recommended parameters are based on data from McCabe et al.<sup>13</sup> and Liu and Sander,<sup>12</sup> because these two comprehensive studies extended to much lower temperatures than the others. The parameters were obtained by assuming the k<sub>∞</sub> parameters are the same as the previous recommendation and that the relative errors are constant, and then carrying out least squares fits; the results from the two data sets were averaged. Pressure and temperature dependent data from McCabe et al.,<sup>13</sup> Hynes et al.,<sup>10</sup> and Liu and Sander<sup>12</sup> are well represented by the recommended parameters. This reaction has been studied by many workers. In general the results are in keeping with the current recommendation. Values have been reported by Dreier and Wolfrum,<sup>7</sup> Husain et al.,<sup>9</sup> Ravishankara and Thompson,<sup>21</sup> Paraskevopoulos and Irwin,<sup>19</sup> Hofzumahaus and Stuhl.<sup>8</sup> The results of Jonah et al.<sup>11</sup> are too high and were not included. An increase in k with pressure has been observed by a large number of investigators: Overend and Paraskevopoulos,<sup>17</sup> Perry et al.,<sup>20</sup> Chan et al.,<sup>4</sup> Biermann et al.,<sup>2</sup> Cox et al.,<sup>5</sup> Butler et al.,<sup>3</sup> Paraskevop and Irwin,<sup>18,19</sup> DeMore,<sup>6</sup> Hofzumahaus and Stuhl,<sup>8</sup> Hynes et al.,<sup>10</sup> McCabe et al.,<sup>13</sup> and Liu and Sander.<sup>12</sup> In addition, Niki et al.<sup>16</sup> have measured k relative to OH + C<sub>2</sub>H<sub>4</sub> in one atmosphere of air by following CO<sub>2</sub> production using FTIR. Previous controversy regarding the effect of small amounts of O<sub>2</sub> (Biermann et al.<sup>2</sup>) has been resolved and is attributed to secondary reactions (DeMore,<sup>6</sup> Hofzumahaus and Stuhl<sup>8</sup>). Liu and Sander<sup>12</sup> has demonstrated that modest levels of O<sub>2</sub> do not interfere with measuring the total rate constant. Currently, there are no indications to suggest that the presence of O<sub>2</sub> has any effect on the rate coefficient other than as a third body. The results of Butler et al.<sup>3</sup> have to be re-evaluated in the light of refinements in the rate coefficient for the OH + H<sub>2</sub>O<sub>2</sub> reaction; the corrected rate coefficient is in approximate agreement with the recommended value. Beno et al.<sup>1</sup> observe an enhancement of k with water vapor, which is in conflict with the flash photolysis studies; e.g., Ravishankara and Thompson,<sup>21</sup> Paraskevopoulos and Irwin,<sup>19</sup> Hynes et al.,<sup>10</sup> and McCabe et al.<sup>13</sup> Water is not expected to significantly change the rate coefficient for the reaction in the atmosphere and it is not expected to alter the products of the reaction. Troe<sup>23</sup> has carried out extensive theoretical analysis of this reaction system. Senosian et al.<sup>22</sup> performed empirical master equation calculations on a theoretical potential energy surface. (The value of the exponent of k<sub>∞</sub> for the chemical activation pathway has a sign error in the reference.) The recent fully *ab initio* calculations of Nguyen et al.<sup>15</sup> (also Weston et al.<sup>24</sup>) fitted from 175–300 K predict k<sub>∞</sub>(300) =  $7.4 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , n = -1.50 (which can be compared with the first line of entries for this reaction in Table 2), and k<sub>bim</sub>(300) =  $1.4 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , n<sub>bim</sub> = -0.44 (which can be compared with the first two entries on the second line); all of these parameters are in very good agreement with the recommended values.

**Important:** For practical applications in Earth's atmosphere, the total rate constant is well-represented as the sum of a bimolecular reaction and a termolecular reaction. To calculate rate constants for the termolecular reaction (i.e. OH +

$\xrightarrow{\text{M}}$  HOCO), use the standard expression for termolecular reactions, k<sub>f</sub>([M], T), given in the Introduction (Section 2.1), and the data on the first line of the entry for this reaction in Table 2. To calculate rate constants k<sub>bim</sub>(T) for the bimolecular reaction (i.e. OH + CO → H + CO<sub>2</sub>), use k<sub>bim</sub>(T) = k<sub>0</sub>(300) × (T/300)<sup>-n</sup> with parameters taken from the second line in the table entry. For rate constants and branching ratios that are more accurate, use k<sub>f</sub>([M], T) together with the expression for chemical activation reactions, k<sub>f</sub><sup>ca</sup>([M], T), given in the Introduction (Section 2.1).

**D2. CH<sub>3</sub> + O<sub>2</sub>.** Data from Kaiser<sup>5</sup> are fit to the NASA format. The ranges of this study were 3 < P/Torr < 11000 and 264 < T/K < 370. The rate constant was measured relative to the reaction CH<sub>3</sub> + Cl<sub>2</sub> → CH<sub>3</sub>Cl + Cl, k/cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> = 1.61 × 10<sup>-12</sup>exp(-530/RT). The recommended values are in good agreement with those from Selzer and Bayes.<sup>12</sup> These workers determined the rate constants as a function of pressure in N<sub>2</sub>, Ar, O<sub>2</sub>, and He. Plumb and Ryan<sup>10</sup> report a value in He which is consistent within error limits with the work of Selzer and Bayes. Pilling and Smith<sup>9</sup> have measured this process in Ar (32–490 Torr). Cobos et al.<sup>2</sup> have made measurements in Ar and N<sub>2</sub> from 0.25 to 150 atmospheres. They report parameters somewhat different than recommended here. The work of Laguna and Baughcum<sup>7</sup> seems to be in the fall-off region. Results of Pratt and Wood<sup>11</sup> in Ar are consistent with this recommendation, although the measurements are indirect. The suggested value accommodates the values of Keiffer et al.,<sup>6</sup> who measured the process in Ar between 20 and 600 Torr and in the range 334 < T/K < 582. Data of van den Bergh and Callear,<sup>13</sup> Hochanadel et al.,<sup>4</sup> Basco et al.,<sup>1</sup> Washida and Bayes,<sup>15</sup> Laufer and Bass,<sup>8</sup> and Washida<sup>14</sup> are also considered. A theoretical study by Zhu et al.<sup>16</sup> is in reasonable agreement with the recommendation. A study by Fernandes et al.<sup>3</sup> at pressures from 2–1000 bar and temperatures between 300 and 700 K presents a parameterization of the rate constant as a function of pressure and temperature which is in agreement with this recommendation at 300 K. If their parameters are used at 200 K the agreement is not as good, but is within the 95% uncertainty limit.

- D3.  $\text{C}_2\text{H}_5 + \text{O}_2$ .** Kaiser et al.<sup>2</sup> extract from a relative rate study:  $k_\infty = (9.2 \pm 0.9) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  and  $k_0 = (6.5 \pm 2.0) \times 10^{-29} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$  in He at 298 K and pressures between 3 and 1500 Torr.  $k_\infty$  has been calculated by Wagner et al.,<sup>6</sup> Miller and Klippenstein,<sup>3</sup> and Sheng et al.<sup>5</sup> with  $k_\infty(300 \text{ K}) = 8$ , 10, and  $4 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , respectively. Although all cite some small temperature dependence, the values are stated to hold above 300 K. The Kaiser et al.,<sup>2</sup> extrapolation to the low-pressure limit is difficult due to the complex potential energy surface, but agrees with a Patrick and Golden-type calculation<sup>4</sup> using  $\Delta H_0^0 = 32.4 \text{ kcal mol}^{-1}$ . The recommended values use the calculated temperature dependence and a 2.5 times higher rate constant for air as the bath gas, in line with suggestions in Kaiser et al.<sup>1</sup>

Phys. Chem. A* **2002**, *106*, 7276–7293, doi:10.1021/jp014540+.
- (6) Wagner, A. F.; Slagle, I. R.; Sarzynski, D.; Gutman, D. Experimental and theoretical studies of the  $\text{C}_2\text{H}_5 + \text{O}_2$  reaction kinetics. *J. Phys. Chem.* **1990**, *94*, 1853–1864.
- D4.  $\text{OH} + \text{C}_2\text{H}_2$ .** The rate constant for this complex process has been examined by Smith et al.<sup>13</sup> in the temperature range from 228 to 1400 K, and in the pressure range 1 to 760 Torr. Their analysis, which is cast in similar terms to those used here, is the source of the rate constants and temperature dependences at both limits. The negative value of m reflects the fact that their analysis includes a 1.2 kcal/mol barrier for the addition of OH to  $\text{C}_2\text{H}_2$ . The data analyzed include those of Pastrana and Carr,<sup>1</sup> Perry et al.,<sup>10</sup> Michael et al.,<sup>8</sup> and Perry and Williamson.<sup>11</sup> Other data of Wilson and Westenberg,<sup>16</sup> Breen and Glass,<sup>3</sup> Smith and Zellner,<sup>14</sup> and Davis et al.<sup>4</sup> were not included. Studies by Liu et al.<sup>7</sup> and Lai et al.<sup>6</sup> are in general agreement with the recommendation. Calculations of  $k_0$  via the methods of Patrick and

Golden<sup>9</sup> yield values compatible with those of Smith et al.<sup>13</sup> A study by Sørensen et al.<sup>15</sup> at 298 K and pressures from 25 to 8000 Torr of bath gas suggests  $k_0/\text{cm}^6 \text{molecule}^{-2} \text{s}^{-1} = 2.92 \times 10^{-30}$ ,  $k_\infty/\text{cm}^3 \text{molecule}^{-1} \text{s}^{-1} = 9.69 \times 10^{-13}$  and  $F_c = 0.6$ . No difference was found between air, N<sub>2</sub>/O<sub>2</sub> mixtures or O<sub>2</sub> as the bath gas. These values yield rate constants as a function of pressure at 298 K in agreement with this recommendation, so the recommended values are unchanged from JPL 02-25. Earlier, Fulle et al.<sup>5</sup> reported a high pressure limiting rate constant of  $2 \times 10^{-12} \text{ cm}^3 \text{molecule}^{-1} \text{s}^{-1}$ , which is the basis for the IUPAC<sup>2</sup> recommendation. A theoretical study by Senosiain et al.<sup>12</sup> is in essential agreement with this recommendation.

**D5. OH + C<sub>2</sub>H<sub>4</sub>.** The recommendation for the low pressure limit at 300 K is the average of fitted values from studies carried out over a significant range of pressure using synthetic air (Klein et al.<sup>9</sup>), N<sub>2</sub> (Vakhtin et al.<sup>17</sup> and Cleary et al.<sup>2</sup>), or Argon (Klein et al.<sup>9</sup>). All three colliders were treated as equivalent. The recommended temperature exponent (n) was taken from the master equation analysis by Golden,<sup>6</sup> who fitted the experimental rate constants in N<sub>2</sub>, including those at very low temperatures (96, 110, and 165 K) reported by Vakhtin et al.<sup>17</sup> The recommendation for the high pressure limit at 300 K is the average of fitted values from eight data sets measured near 300 K using helium (Tully et al.,<sup>16</sup> Kuo and Lee,<sup>10</sup> and Cleary et al.<sup>2</sup>), argon (Klein et al.<sup>9</sup>), N<sub>2</sub> (Vakhtin et al.<sup>17</sup> and Cleary et al.<sup>2</sup>), and synthetic air (Klein et al.<sup>9</sup>). The recommended temperature exponent was from a least squares fit of the high pressure limiting values obtained from individual fits of data at 15 temperatures ranging from 200 K to 430 K, including data near 300 K.<sup>2,9,10,16,17</sup> In addition to the studies already mentioned, the recommended high pressure rate constants are in good agreement with the data of Davis et al.,<sup>4</sup> Howard,<sup>8</sup> Greiner,<sup>7</sup> Morris et al.,<sup>12</sup> and Overend and Paraskevopoulos<sup>13</sup> in helium, Atkinson et al.<sup>1</sup> in argon, and Lloyd et al.<sup>11</sup> and Cox<sup>3</sup> in nitrogen/oxygen mixtures. The parameters recommended are similar to the curve proposed by Klein et al.<sup>9</sup> at 298 K. Kuo and Lee<sup>10</sup> report a stronger temperature dependence for the low-pressure limit (n=4), but the present recommendation is in good agreement with their

measured rate constants. Calculations of the type in Patrick and Golden<sup>14</sup> as described in Vakhtin et al.<sup>17</sup> yield  $n = 4.2$ , although they use a somewhat low value for energy transfer by nitrogen. The high-pressure limit temperature dependence has been determined by several workers. Zellner and Lorenz<sup>18</sup> report a value equivalent to  $m = +0.8$  over the range ( $296 < T/K < 524$ ) at about 1 atmosphere. A value of  $m = +2.0$  fits the data ( $540 < T/K < 670$ ) of Diau and Lee.<sup>5</sup> Cleary et al.<sup>2</sup> report values in  $N_2$  at 295 K. They also report values in He between 200 and 400 K. They perform master equation calculations and report fitting parameters. Taylor et al.<sup>15</sup> report data at a single pressure and 69 and 86 K. Their data are well-accommodated by this recommendation and by the parameters in Cleary et al.<sup>2</sup> (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- D6. OH + CH<sub>3</sub>CH=CH<sub>2</sub> (propene).** The following studies have been used to reach the recommendation: Spangenberg et al.<sup>10</sup> in a Laval nozzle expansion of  $N_2$  with LIF detection of OH at 293 K and at individual points from 114 to 58 K; Vakhtin et al.<sup>12,13</sup> in a Laval nozzle expansion of  $N_2$  with LIF detection of OH at 296 K and individual points at 96, 110, and 165 K; Nielsen et al.<sup>6</sup> in a pulse radiolysis experiment (kinetic UV absorbance of OH radical) at 298 K in 1 atm of air; Wallington<sup>14</sup> in a pulsed laser photolysis experiment with LIF detection of OH at 298 K in Argon; Schmidt et al.<sup>9</sup> with laser photolysis and LIF of OH at 295 K in 1 atm of air; Tully and Goldsmith<sup>11</sup> with laser photolysis and LIF detection of OH at 293 to 467 K in 25 to 600 Torr of He; Zellner and Lorenz<sup>15</sup> laser photolysis and resonance fluorescence detection of OH at 297 K in 1.3–130 mbar of Ar; Klein et al.<sup>4</sup> with a relative rate measurement (relevant to n-Hexane) at 295 K in 1.3–1000 mbar of air; Atkinson and Aschmann<sup>1</sup> from relative rate measurements at 295 K in

1 atm of air; Nip and Paraskevopoulos<sup>7</sup> with flash photolysis and resonance absorption at 297 K in 75 mbar of an H<sub>2</sub>/N<sub>2</sub>O mixture; Ravishankara et al.<sup>8</sup> with flash photolysis and resonance fluorescence of OH at 295 K in 20 and 200 Torr of He; and Atkinson and Pitts<sup>2</sup> by flash photolysis and resonance fluorescence of OH at 298–425 K in 25–100 Torr of Ar. Additional studies have been reviewed by Calvert et al.<sup>3</sup> The recommended high pressure rate constant at 298 K is the geometric mean of all of the studies listed above, except for the relative rate measurement of Klein et al.<sup>4</sup> The temperature exponent of k<sub>∞</sub> (parameter m) is the average of the values obtained from weighted least squares fits of data from Tully and Goldsmith<sup>11</sup> and from Vakhtin et al.;<sup>13</sup> the former extends upward from ~300 K and the latter extends downward. Pressure fall-off is only apparent at lower pressures and higher temperatures; most studies did not observe significant fall-off. Usable fall-off data near 300 K are available from Klein et al.<sup>4</sup> (Ar bath gas), Zellner and Lorenz<sup>15</sup> (Ar bath gas), and Vakhtin et al.<sup>13</sup> (N<sub>2</sub> bath gas). These fall-off data sets are for two different collider gases and provide only rough estimates of k<sub>0</sub>(298); the error factor associated with k<sub>0</sub> is at least ×3. Because no temperature-dependent fall-off data are available, the recommendation for the temperature exponent (parameter n) is based on the estimate by Calvert et al.<sup>3</sup> Loison et al.,<sup>5</sup> using a fast flow reactor coupled to a time of flight mass spectrometer, found that 71 ± 16% of the reaction near room temperature proceeds by addition of the OH to the terminal CH<sub>2</sub> group.

- D7. OH + CH<sub>2</sub>=C(CH<sub>3</sub>)CH<sub>3</sub> (*iso*-butene).** The rate constant is not dependent on pressure even at 1 Torr of helium, suggesting that it is very near the high pressure limit in all of the reported studies. The recommended high pressure rate constant at 298 K is the geometric mean of the absolute rate constants reported by Atkinson and Pitts (flash photolysis (FP) with resonance fluorescence (RF) detection of OH)<sup>2</sup> and relative rate measurements reported by Wu et al.<sup>8</sup> (cited by Calvert et al.<sup>4</sup>), Barnes et al.,<sup>3</sup> Ohta,<sup>6</sup> and Atkinson and Aschmann.<sup>1</sup> The recommendation is in fair agreement with the early discharge-flow measurement of Morris and Niki.<sup>5</sup> The temperature dependence is based on

the measurements of Atkinson and Pitts.<sup>2</sup> The estimated  $2\sigma$  error limits are set to include all of the data used in the recommendation; because there is only one study of temperature dependence, f(298) and g were set to 1.2 and 200, respectively. Calvert et al.<sup>4</sup> reviewed the data published prior to 2000 and recommended rate constants in reasonable agreement with the present recommendation. The reaction proceeds mostly (>90%) by addition of OH to the two carbon atoms at the ends of the double bond.<sup>4</sup> Peeters et al.<sup>7</sup> reported that  $85 \pm 10\%$  of the addition is to the terminal carbon atom, producing a tertiary free radical (the balance produces a primary free radical).

- D8. OH + CH<sub>2</sub>=CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> (1-butene).** The rate constant is not dependent on pressure even at 1 Torr of helium, suggesting that it is very near the high pressure limit in all of the studies. The recommended high pressure rate constant at 298 K is the geometric mean of the absolute rate constants reported by Atkinson and Pitts<sup>2</sup> (flash photolysis (FP) with resonance fluorescence (RF) detection of OH), Ravishankara et al.<sup>13</sup> (FP-RF), Nip and Paraskevopoulos<sup>9</sup> (FP with resonance absorption (RA) detection of OH), Biermann and Pitts<sup>4</sup> (discharge flow (DF) with mass spectrometry (MS) detection), Sims et al.<sup>14</sup> (Laval-Nozzle flow apparatus (LN) and laser induced fluorescence (LIF) detection of OH), Vakhtin et al.<sup>15</sup> (LN-LIF), and relative rate measurements reported by Wu et al.<sup>17</sup> (cited by Calvert et al.<sup>5</sup>), Lloyd et al.,<sup>6</sup> Winer et al.,<sup>16</sup> Barnes et al.,<sup>3</sup> Ohta,<sup>10</sup> and Atkinson and Aschmann.<sup>1</sup> The recommendation is in good agreement with the early discharge-flow measurement of Morris and Niki,<sup>8</sup> and in poor agreement with that of Pastrana and Carr,<sup>11</sup> which possibly was affected by secondary reactions. The temperature dependence is based on the measurements of Atkinson and Pitts,<sup>2</sup> Sims et al.,<sup>14</sup> and Vathkin et al.<sup>15</sup> Calvert et al. reviewed the data published prior to 2000 and recommended rate constants<sup>5</sup> in good agreement with the present recommendation. The estimated  $2\sigma$  error limits are set to include all of the data used in the recommendation. The reaction proceeds mostly (>90%) by addition of OH to the two carbon atoms at the ends of the double bond.<sup>5</sup> Peeters et al.<sup>12</sup> measured product branching ratios in a multi-stage flow apparatus with mass spectrometric detection and concluded that  $85 \pm 10\%$  of the OH addition reaction proceeds by addition to the terminal CH<sub>2</sub> group, producing a secondary free radical. Peeters et al. also developed a structure–activity relationship (SAR) for predicting the product distribution for OH + alkene reactions. Loison et al.<sup>7</sup> also used a flow apparatus with mass spectrometric detection, but with photoionization, and reported that  $71 \pm 16\%$  of the addition reaction is to the terminal CH<sub>2</sub> group, in good agreement with Peeters et al. Furthermore, Loison et al. concluded that  $8 \pm 3\%$  of the total reaction is due to abstraction.

**D11. CH<sub>3</sub>O + NO.** This reaction proceeds via a complex potential energy surface that includes both chemical activation and direct abstraction routes<sup>1</sup> to the disproportionation products CH<sub>2</sub>O and HNO as well as the combination to form CH<sub>3</sub>NO. The chemical activation process would have inverse pressure dependence and the direct abstraction would be pressure independent. The recommended values take into account the results of Frost and Smith<sup>4</sup> in Ar and CF<sub>4</sub> and of Caralp et al.<sup>1</sup> in He and Ar. In both of these references the disproportionation process is subtracted from total loss of CH<sub>3</sub>O with a pressure independent, temperature dependent value. At 300 K below one Torr the disproportionation process dominates. Temperature dependences are from the higher temperature results. The low pressure rate constant is consistent with the measurements of McCaulley et al.<sup>5</sup> and Daële et al.<sup>2</sup> in helium. Studies by Ohmori et al.<sup>6</sup> and Dobé et al.<sup>3</sup> are in general agreement with respect to both the addition and bimolecular pathways. (See the note in Table 1-1 for the bimolecular pathway.)

**D13.  $\text{C}_2\text{H}_5\text{O} + \text{NO}$ .** High-pressure data at 298 K in Ar from Frost and Smith<sup>3</sup> and in He between 286 and 388 K at pressures from 30 to 500 Torr, from Fitschen et al.<sup>2</sup> Low-pressure measurements in He are from Daele et al.<sup>1</sup> He experiments were scaled to  $\text{N}_2$  by dividing by a factor of 2.5. Ar data were taken as equivalent to  $\text{N}_2$  or air. The data were fit by subtracting an assumed pressure independent value of  $1 \times 10^{-11}$  from the measured rate constants to account for the route to form  $\text{HNO}$  and  $\text{CH}_3\text{CHO}$ . The low pressure value agrees with theory. The bimolecular channel with an estimated rate constant of about  $10^{-11}$  needs to be verified by direct studies. The temperature dependence of the low pressure limit is estimated and that of the high pressure limit is taken from Fitschen et al.<sup>2</sup> (The high pressure rate expression in Fitschen et al. seems to be in error.) **D14.  $\text{C}_2\text{H}_5\text{O} + \text{NO}_2$ .** High-pressure rate constant at 298 K from Frost and Smith.<sup>1</sup> Other values estimated from similar reactions. (Table: 06-2, Note: 92-20, Evaluated: 06-2) [Back to Table](#)

- (1) Frost, M. J.; Smith, I. W. M. Rate constants for the reactions of  $\text{CH}_3\text{O}$  and  $\text{C}_2\text{H}_5\text{O}$  with  $\text{NO}_2$  over a range of temperature and total pressure. *J. Chem. Soc. Faraday Trans.* **1990**, *86*, 1751-1756.

**D15.  $\text{CH}_3\text{O}_2 + \text{NO}_2$ .** Golden<sup>3</sup> has re-evaluated the data for this reaction. The recommended parameters are from a fit to Percival<sup>4</sup> and temperature- and pressure-dependent data in Sander and Watson<sup>6</sup> and Ravishankara et al.<sup>5</sup> The temperature dependence of the high pressure rate constant is a little high, but results from the statistical fit to the data. The values recommended herein, were taken with the data in a study of the reverse reaction by Zabel et al.<sup>7</sup> to compute the value of the equilibrium constant in Table 3-1. Destriau and Troe<sup>2</sup> have fit the above data with  $k_\infty$  independent of temperature and  $F_c = 0.36$ . Bridier et al.<sup>1</sup> are in good agreement with this recommendation at one atmosphere and 298 K.

**D16.  $\text{C}_2\text{H}_5\text{O}_2 + \text{NO}_2$ .** The only experimental study is that of Elfers et al.<sup>3</sup> who measured the rate constant relative to the  $\text{C}_2\text{H}_5\text{O}_2 + \text{NO}$  reaction between 10 and 1000 mbar. Elfers et al. used a value of  $k = 8.9 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  for the reference reaction. By comparison the recommended rate constant for the reference reaction from Table 1-1 of this evaluation is  $1.1 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  at 254 K. There are three data points. An evaluation of the Elfers et al. work by Destriau and Troe<sup>2</sup> cast the data in the format used in the IUPAC evaluation.<sup>1</sup> The parameters in Table 2 are adjusted to agree with the data corrected for the change in the reference reaction, using the simpler formula employed in this recommendation.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

**D17.  $\text{CH}_3\text{C(O)O}_2 + \text{NO}_2$ .** The recommended parameters are from the data of Bridier et al.,<sup>1</sup> who report in the format represented here, but using  $F_c = 0.3$ . Their values are:  $k_0^{300} = (2.7 \pm 1.5) \times 10^{-28}$ ,  $k_\infty^{300} = (12.1 \pm 2.0) \times 10^{-12}$ , with  $n = 7.1 \pm 1.7$  and  $m = 0.9 \pm 0.15$ . Studies of the decomposition of  $\text{CH}_3\text{C(O)O}_2\text{NO}_2$  [PAN] by Roberts and Bertman,<sup>4</sup> Grosjean et al.,<sup>2</sup> and Orlando et al.<sup>3</sup> are in accord with those of Bridier et al.<sup>1</sup> In the Roberts and Bertman<sup>4</sup> study it was shown that PAN decomposition yields only peroxyacetyl radical and  $\text{NO}_2$ ; no methyl nitrate. Studies by Seefeld et al.<sup>5</sup> and Sehested et al.<sup>6</sup> of the relative rates of  $\text{CH}_3\text{C(O)O}_2$  with NO and  $\text{NO}_2$  are confirmatory. A study by von Ahsen et al.<sup>7</sup> involving matrix isolation of the products of PAN decomposition, suggests a minor pathway due to O-O bond fission.

**D18.  $\text{CH}_3\text{CH}_2\text{C}(\text{O})\text{O}_2 + \text{NO}_2$ .** This reaction, forming peroxypropionyl nitrate (PPN), has been studied in the reverse direction by Schurath and Wipprecht,<sup>4</sup> Mineshos and Glavas,<sup>3</sup> Grosjean et al.,<sup>1</sup> and Kirchner et al.<sup>2</sup> Group additivity considerations indicate that the equilibrium constant for both PAN and PPN will be the same (both sides of the equilibrium for PPN differ from those for PAN by the group C-(C)(CO)(H)<sub>2</sub>). Therefore, the recommended value for the association reaction is taken from the decomposition studies multiplied by the same equilibrium constant as for PAN. The resulting values are very similar to those for  $\text{CH}_3\text{C}(\text{O})\text{O}_2 + \text{NO}_2$  forming peroxyacetyl nitrate (PAN). Conservative error limits are estimated.

**D19.  $\text{CH}_3\text{C}(\text{O})\text{CH}_2 + \text{O}_2$ .** Cox et al.<sup>1</sup> reported a value of  $k = (1.5 \pm 0.3) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  at 298 K and 1 atm of SF<sub>6</sub> in which a pulse radiolysis study was modeled. Studies in He at 298 K have been reported by Oguchi et al.,<sup>5</sup> Imrik et al.,<sup>3</sup> Kovacs et al.,<sup>4</sup> and Hassouna et al.<sup>2</sup> This data can be accommodated with  $k_0 = 1.5 \times 10^{-29} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ ,  $k_\infty = 1.0 \times 10^{-12} \text{ s}^{-1}$  with  $f = 1.15$ . To account for the difference between He and N<sub>2</sub>,  $k_0 = 3 \times 10^{-29}$ , and  $f = 1.3$  are estimated and recommended. Hassouna et al. report rate constants in the temperature range 291 to 400 K at 130 and 650 bar He showing a slight negative temperature dependence. They also report data at 10 bar He in the temperature range 459 to 520 K. These latter data exhibit biexponential decays from which the equilibrium constant is also extracted. (See Table 3-1.)

**D20.  $\text{CH}_2\text{OO} + \text{CH}_2\text{OO}$  (Criegee intermediate).** The recommendation is the average of the rate constants reported near 298 K by Buras et al.<sup>1</sup> and Ting et al.<sup>6</sup> (the latter supersedes the report of Su et al.<sup>5</sup>). The reaction does not depend on pressure at least up to 1 atmosphere, because of the existence of low energy thresholds for subsequent isomerization and fragmentation.<sup>7</sup> The reaction products are thought to be 2 H<sub>2</sub>CO + O<sub>2</sub>(<sup>1</sup> $\Delta_g$ ). Because of the rapid reactions of CH<sub>2</sub>OO and the complex mixtures of reactants present in the systems that have been studied, rate constants must be extracted from complicated mechanisms.<sup>1-4,6,7</sup> Ting et al.<sup>6</sup> have presented an analysis using perhaps the most comprehensive mechanism to date, but this field is changing very rapidly.

**E1. F + O<sub>2</sub>.** Values are taken from a study by Campuzano-Jost et al.,<sup>2</sup> with experiments from 100 to 420 K at pressures of He, Ar and N<sub>2</sub> from 1 to 1000 bar. (They used  $F_c = 0.54(T/300)^{-0.09}$ , but the results are essentially the same with  $F_c = 0.6$ .) A study by Pagsberg et al.<sup>7</sup> reports  $k_0$  in argon =  $4.38 \times 10^{-33} (T/300)^{-1.2}$ . There is also good agreement with earlier values of Smith and Wrigley,<sup>9</sup> Smith and Wrigley,<sup>10</sup> Shamonina and Kotov,<sup>8</sup> Arutyunov et al.,<sup>1</sup> Wallington and Nielsen,<sup>12</sup> Wallington et al.,<sup>11</sup> and Ellerman et al.<sup>5</sup> The values are slightly lower than the values of Chen et al.<sup>4</sup> and Chegodaev et al.<sup>3</sup> Lyman and Holland<sup>6</sup> report a slightly lower value in Ar at 298 K. Campuzano-Jost et al.<sup>2</sup> and Pagsberg et al.<sup>7</sup> also determined the equilibrium constant and thus  $\Delta H_{f,298}(\text{FO}_2) = 6.13 \pm 0.5 \text{ kcal mol}^{-1}$ . See F + O<sub>2</sub> in Table 3-1.

**E3. F + NO<sub>2</sub>.** Fasano and Nogar<sup>3</sup> studied this reaction in N<sub>2</sub> at 300 K. Pagsberg et al.<sup>5</sup> studied the reaction in SF<sub>6</sub> and Zetzsch<sup>7</sup> studied it in He. The results from Fasano and Nogar<sup>3</sup> and Pagsberg et al.<sup>5</sup> were used to determine both the high and low pressure limits at 300 K. Treatment of the data for this system requires knowledge of the relative stabilities of FNO<sub>2</sub> and FONO. Patrick and Golden<sup>6</sup> assumed that the difference between these would be the same as between the ClNO<sub>2</sub> isomers. Theoretical work by Dixon and Christie,<sup>2</sup> Lee and Rice,<sup>4</sup> and Amos et al.<sup>1</sup> indicates that FNO<sub>2</sub> is 35–40 kcal mol<sup>-1</sup> more stable than FONO, and therefore the measured rate refers to FNO<sub>2</sub> formation. The value of n = 2 is from Patrick and Golden, but consistent with Pagsberg et al.<sup>5</sup> who made a few measurements at 341 K. The value of m is a rough estimate from similar reactions, but is also consistent with Pagsberg et al.<sup>5</sup>

**E5. CF<sub>3</sub> + O<sub>2</sub>.** Caralp et al.<sup>3</sup> have measured the rate constant in N<sub>2</sub> between 1 and 10 Torr. This supersedes the value from Caralp and Lesclaux.<sup>2</sup> Kaiser et al.<sup>5</sup> have extended the pressure range to 580 Torr measuring the reaction relative to the reaction of CF<sub>3</sub> with Cl<sub>2</sub>. Breheny et al.<sup>1</sup> report values at 295 K from 2–110 Torr and they make a cogent argument for lowering the value of the rate constant used by Kaiser et al for their reference reaction by about 50%. This has the effect of lowering the Kaiser values. Each study recommends different parameters, but the data are well represented by the currently recommended values. Data of Ryan and Plumb<sup>6</sup> are in general agreement. Forst and Caralp<sup>4</sup> have examined this reaction theoretically.

- (5) Kaiser, E. W.; Wallington, T. J.; Hurley, M. D. Kinetic study of the reaction of chlorine atoms with  $\text{CF}_3\text{I}$  and the reactions of  $\text{CF}_3$  radicals with  $\text{O}_2$ ,  $\text{Cl}_2$  and  $\text{NO}$  at 296 K. *Int. J. Chem. Kinet.* **1995**, *27*, 205-218.
- (6) Ryan, K. R.; Plumb, I. C. Kinetics of the reactions of  $\text{CF}_3$  with  $\text{O}(\text{P}^3)$  and  $\text{O}_2$  at 295 K. *J. Phys. Chem.* **1982**, *86*, 4678-4683, doi:10.1021/j100221a008.

**E6.  $\text{CF}_3\text{O} + \text{NO}_2$ .** Fockenberg et al.<sup>2</sup> report values (and large error limits) in nitrogen with  $250 < T/\text{K} < 302$  and  $7 < P/\text{mbar} < 107$ . Their values, including two sigma errors are:  $k_0 = (3.1 \pm 3.0) \times 10^{-28}$ ;  $n = (2.0 \pm 2.0)$ ;  $k_\infty = (1.5 \pm 0.5) \times 10^{-28}$ ;  $m = (2.8 \pm 2.0)$ . Because such large values for  $m$  are not physically justifiable, the recommendation is based on a fit forcing  $m = 1$ , which falls within the large error limits. The reaction products reported by Fockenberg et al. agree with those reported by Chen et al.,<sup>1</sup> who used photolysis of  $\text{CF}_3\text{NO}$  to prepare  $\text{CF}_3\text{O}_2$  and subsequently  $\text{CF}_3\text{O}$  in 700 Torr of air at  $297 \pm 2$  K. They considered two product channels: (a)  $\text{CF}_3\text{ONO}_2$  obtained via three-body recombination and (b)  $\text{CF}_2\text{O} + \text{FNO}_2$  obtained via fluorine transfer. Both products were observed and found to be thermally stable in their reactor. They report  $k_a/(k_a+k_b) > 90\%$  and  $k_b/(k_a+k_b) < 10\%$ , thus the formation of  $\text{CF}_3\text{ONO}_2$  is the dominant channel at 700 Torr and 297 K.

- (2) Fockenberg, C.; Somnitz, H.; Bednarek, G.; Zellner, R. Kinetic and mechanistic studies of the reactions of  $\text{CF}_3\text{O}$  radicals with NO and  $\text{NO}_2$ . *Ber. Bunsenges. Phys. Chem.* **1997**, *101*, 1411-1420.

**E7.  $\text{CF}_3\text{O}_2 + \text{NO}_2$ .** The data are from experiments in  $\text{O}_2$  of Caralp et al.,<sup>1</sup> who suggest a somewhat different fitting procedure than used here. A statistical best fit to the data yields a value of  $m = 5.7$ , but the values recommended here fit the data just about as well. Destriau and Troe<sup>2</sup> use yet a different fitting procedure that does not represent the data quite as well as that recommended here. Reverse rate data are given by Köppenkastrop and Zabel.<sup>3</sup>

**E8.  $\text{CF}_3\text{O} + \text{CO}$ .** Values taken from Turnipseed et al.<sup>1</sup> The numbers were obtained for Ar as the bath gas and are assumed to hold for  $\text{N}_2$  as well. The temperature dependence of the high-pressure rate constant was determined over the range  $233 < T/\text{K} < 332$  in  $\text{SF}_6$ . No temperature dependence of the low-pressure-limiting rate constant was reported. The value in the table is an estimate. Wallington and Ball<sup>2</sup> report values in good agreement with Turnipseed et al.<sup>1</sup>

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Turnipseed, A. A.; Barone, S. B.; Jensen, N. R.; Hanson, D. R.; Howard, C. J.; Ravishankara, A. R. Kinetics of the reactions of  $\text{CF}_3\text{O}$  radicals with CO and  $\text{H}_2\text{O}$ . *J. Phys. Chem.* **1995**, *99*, 6000-6009.
- (2) Wallington, T. J.; Ball, J. C. Phys. Chem.* **1995**, *99*, 3201-3205, doi:10.1021/j100010a034.

**E9.  $\text{CF}_3\text{O} + \text{M}$ .** The activation energy for thermal decomposition of  $\text{CF}_3\text{O}$  to  $\text{CF}_2\text{O} + \text{F}$  has been reported to be 31 kcal mol<sup>-1</sup> by Kennedy and Levy.<sup>1</sup> Thermochemical data yield  $\Delta\text{H}^\circ(298) = 23$  kcal mol<sup>-1</sup>. This implies an intrinsic barrier of about 8 kcal mol<sup>-1</sup> to elimination of F from  $\text{CF}_3\text{O}$ . Electronic structure calculations by Li and Francisco<sup>2</sup> support this observation. Adopting the A-factor for unimolecular dissociation,  $A = 3 \times 10^{14} \text{ s}^{-1}$  and  $E = 31$  kcal mol<sup>-1</sup> from Kennedy and Levy,  $k_\infty(298 \text{ K})$  is about  $6 \times 10^{-9} \text{ s}^{-1}$ . This corresponds to a lifetime of about 6 years; therefore, thermal decomposition of  $\text{CF}_3\text{O}$  is unimportant throughout the atmosphere.

**F1. Cl + O<sub>2</sub>.** Nicovich et al.<sup>3</sup> measured the rate constant at  $181 < T/K < 200$  and  $15 < P/\text{Torr} < 40$  in O<sub>2</sub>. They reported  $k_0 = (9 \pm 3) \times 10^{-33} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$  at  $T = 187 \pm 6 \text{ K}$  in O<sub>2</sub>. The recommended low pressure limiting parameters are from fitting their data over the entire range and assuming that O<sub>2</sub> and N<sub>2</sub> bath gases are equivalent. The value from the calculation at 300 K (i.e.,  $2.2 \times 10^{-33} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ ) compares with an older value of Nicholas and Norrish<sup>2</sup> of  $1.7 \times 10^{-33}$  in an N<sub>2</sub> + O<sub>2</sub> mixture. Baer et al.<sup>1</sup> report a value in O<sub>2</sub> of  $k_0 = 1.6 \times 10^{-33}(T/300)^{-2.9} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$  in good agreement with the value recommended here. They also report a value in N<sub>2</sub> of  $k_0 = 1.4 \times 10^{-33}(T/300)^{-3.9} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ . A theoretical study by Zhu and Lin<sup>4</sup> suggests  $k_0 = 1.26 \times 10^{-16} T^{-6.22} \exp(-943/T) \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$  in O<sub>2</sub> ( $2.0 \times 10^{-33}$  at 300 K) with  $k_\infty(300) = 1.8 \times 10^{-10} \text{ s}^{-1}$ , which is adopted here. The Nicovich et al.<sup>3</sup> data are so far from the high pressure limit, that the rate constant has little sensitivity to  $k_\infty$ . Baer et al.<sup>1</sup> suggest  $k_\infty = 2.7 \times 10^{-11} \text{ s}^{-1}$ , but the data suggest a higher value.

**F3. Cl + NO<sub>2</sub>.** Low-pressure limit at 300 K from Leu<sup>4</sup> and Ravishankara et al.<sup>7</sup> The latter study extended the data to 200 Torr in He. A turbulent flow study by Seeley et al.<sup>9</sup> extended the results to 250 Torr of Ar and the high-pressure limit was chosen to fit these two studies after taking into account differences in collisional efficiencies of the bath gases. Leu<sup>4</sup> confirms the observation of Niki et al.<sup>5</sup> that both ClONO and ClNO<sub>2</sub> are formed, with the former dominating. This has been explained by Chang et al.,<sup>1</sup> with detailed calculations in Patrick and Golden.<sup>6</sup> The temperature dependence is as predicted in Patrick and Golden<sup>6</sup> and is the same as Leu's results in He. Ravishankara et al.<sup>7</sup> report a few data points in N<sub>2</sub> that may suggest a somewhat higher temperature dependence. The temperature dependence of the high-pressure limit is estimated. The uncertainty limits are estimated. Master Equation/RRKM studies by Zhu and Lin<sup>10</sup> and by Golden,<sup>2</sup> using potential energy surfaces computed by Lee,<sup>3</sup> Zhu and Lin,<sup>10</sup> and Sayin and McKee<sup>8</sup>, report differences in their ability to fit the data. Zhu and Lin<sup>10</sup> claim to fit, while Golden<sup>2</sup> finds the calculations to under predict the low pressure data.

**F5. Cl + C<sub>2</sub>H<sub>2</sub>.** The recommended values are a statistical fit to the work of Kaiser<sup>4</sup> in air. Kaiser and Wallington<sup>3</sup> extends the pressure range at 296 K to 0.3–6000 Torr. The data are in reasonable agreement with earlier measurements of Brunning and Stief<sup>2</sup> and Wallington et al.,<sup>7</sup> although the derived temperature dependence is less than obtained by Brunning and Stief.<sup>2</sup> These values are compatible with earlier studies of Poulet et al.,<sup>6</sup> Atkinson and Aschmann,<sup>1</sup> Lee and Rowland,<sup>5</sup> and Wallington et al.<sup>8</sup> Using FTIR, Zhu et al.<sup>9</sup> reported branching of 16% and 84% to the *trans* and *cis* adduct isomers, respectively, at 700 Torr N<sub>2</sub> and 295 K.

**F8. ClO + NO<sub>2</sub>.** The low-pressure-limit recommendation and uncertainties are based on temperature-dependent values from Zahniser et al.,<sup>13</sup> Lee et al.,<sup>8</sup> Birks et al.,<sup>1</sup> Leu et al.,<sup>9</sup> Wallington and Cox,<sup>12</sup> Cox et al.,<sup>2</sup> and Molina et al.<sup>10</sup> All of these data were collected in N<sub>2</sub> bath gas, except for several points from Lee et al.<sup>8</sup> collected in O<sub>2</sub>. The high-pressure-limit recommendation is based on the RRKM calculations of Smith and Golden.<sup>6</sup> There are several pressure-dependent data sets in the literature, such as Percival et al.,<sup>11</sup> Handwerk and Zellner,<sup>7</sup> Dasch et al.,<sup>4</sup> and Cox and Lewis;<sup>3</sup> however, they are too disparate to extract unambiguous values. These data are all reproduced within two-sigma error limits by the current recommendation. However, the value of m = 1.9 is somewhat large for a radical-radical process. If m = 1 is chosen the computed rate constant is lower by about 20% at 180 K and pressures above 500 Torr. Golden<sup>5</sup> has attempted to fit the data with a master equation analysis and finds that the usual energy transfer treatment at low pressures is insufficient to fit the data.

**F9. OCIO + NO<sub>3</sub>.** Friedl et al.<sup>2</sup> studied this system at  $1 \leq P/\text{Torr} \leq 5$  for helium and  $220 \leq T/K \leq 298$ . They deduced values for the rate constant consistent with their data of  $k_0 \approx 10^{-31}$  and  $k_\infty \approx 10^{-11}$ . They also suggest a value for the equilibrium constant:  $K/\text{cm}^3 \text{ molecule}^{-1} = 1 \times 10^{-28} \exp(9300/T)$ . Boyd et al.<sup>1</sup> raised the question of possible heterogeneous effects in this system. Parthiban et al.<sup>3</sup> in a theoretical study, support the finding of Friedl et al.<sup>2</sup> of the species O<sub>2</sub>ClONO<sub>2</sub>, but suggest a very different equilibrium constant. (See Table 3-1).

- (3) Parthiban, S., T. J. Lee, S. Guha, and J. S. Francisco Theoretical study of chlorine nitrates: Implications for stratospheric chlorine chemistry. *J. Am. Chem. Soc.* **2003**, *125*, 10446-10458, doi:10.1021/ja010297g.

**F10. ClO + ClO.** The recommendation is based on a global non-linear least squares fit (all data were assumed to have the same relative error) of data from Sander et al.<sup>15</sup> (195–247 K), Nickolaisen et al.<sup>13</sup> (260–390 K), Bloss et al.<sup>3</sup> (183–245 K), Trolier et al.<sup>19</sup> (200–263 K), Boakes et al.,<sup>4</sup> and Ferracci and Rowley<sup>7</sup> (250–312 K). The Trolier et al. data have been corrected for values at the zero pressure intercept as suggested in the Trolier et al. paper. With this adjustment most of the data are in reasonable agreement. Boakes et al.<sup>4</sup> report higher values and a zero pressure intercept; they suggest disregarding their data at less than 100 Torr and report preferred parameters of  $2.79 \times 10^{-32}$ ; 3.78;  $3.44 \times 10^{-12}$ ; 1.73. Ferracci and Rowley<sup>7</sup> studied the reaction only at 760 Torr and found values in agreement with those of Boakes et al. The error limits represent an attempt to include most of the data within the 95% uncertainty band. The major dimerization product is chlorine peroxide (Birk et al.,<sup>2</sup> DeMore and Tschiukow-Roux,<sup>6</sup> Slanina and Uhlik,<sup>16</sup> Stanton et al.,<sup>17</sup> and Lee et al.<sup>11</sup>). Golden<sup>8</sup> has performed RRKM and master equation calculations using the potential energy surface in Zhu and Lin<sup>21</sup> and concluded that while a channel to form ClOCIO might exist, the net yield is probably very small the best representation of the data remains that only a single channel is important. The  $k_0$  value for N<sub>2</sub> is not in accord with a simple theory as explained in Patrick and Golden<sup>14</sup> and in some detail in Golden<sup>8</sup> (this finding was probably the result of a bug that was subsequently found in the master equation code). It has been suggested<sup>18</sup> that the “radical-complex” mechanism may apply here, although a study by Liu and Barker<sup>12</sup> suggests otherwise. Other previous rate constant measurements, such as those of Hayman et al.,<sup>9</sup> Cox and Derwent,<sup>5</sup> Basco and Hunt,<sup>1</sup> Walker,<sup>20</sup> and Johnston et al.,<sup>10</sup> range from  $(1\text{-}5) \times 10^{-32}\text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ , with N<sub>2</sub> or O<sub>2</sub> as third bodies.

**F11.  $\text{ClO} + \text{OCIO}$ .** Data are from Burkholder et al.,<sup>1</sup> who measured the rate constant in  $\text{N}_2$  at  $200 \leq T/\text{K} \leq 260$  and densities from  $(1.1\text{--}10.9) \times 10^{18}$  molecules  $\text{cm}^{-3}$ . They also measured the equilibrium constant (See Table 3-1). Parr et al.<sup>3</sup> also report a value for the rate constant in reasonable agreement with the recommendation. Zhu and Lin<sup>4</sup> report an *ab initio* study of this system. Their parameters are somewhat different from those herein, but they fit the data equally well. Green et al.<sup>2</sup> report a value in He that is consistent with the values recommended herein.

**F12.  $\text{O} + \text{OCIO}$ .** The recommendation is based on data of Colussi et al.<sup>2</sup> and Colussi,<sup>1</sup> who measured the pressure dependence between 248 and 312 K in Ar. They interpret the intercept of their  $k$  vs  $[\text{M}]$  curves as a zero-pressure rate constant of  $(1.6 \pm 0.4) \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  with a negative activation energy corresponding to a chemical activation channel producing  $\text{ClO} + \text{O}_2$ . This interpretation is supported by a low pressure study by Gleason et al.,<sup>3</sup> as well as a theoretical study by Zhu and Lin,<sup>4</sup> which suggests a direct abstraction with a positive activation energy. (Zhu and Lin<sup>4</sup> point out that sym- $\text{ClO}_3$  has a positive barrier for dissociation to  $\text{ClO} + \text{O}_2$ .) The recommended values are fit to the data after subtracting the abstraction channel. See Table 1-1.

**F15. CCl<sub>3</sub> + O<sub>2</sub>.** The recommendation incorporates studies by Fenter et al.,<sup>3</sup> Danis et al.,<sup>2</sup> and Luther et al.<sup>5</sup> (The data of Luther et al. above 100 bar are affected by slow diffusion.) Experimental data of Ryan and Plumb<sup>8</sup> have been considered in the evaluation. A study by Nottingham et al.,<sup>6</sup> in He, is in agreement. Forst and Caralp<sup>4</sup> have examined this reaction theoretically. A Patrick and Golden-type calculation using the thermochemistry of Russell et al.<sup>7</sup> yields k<sub>0</sub><sup>300</sup> = 1.5 × 10<sup>-30</sup>, with β = 0.3. A value of k<sub>∞</sub><sup>300</sup> = 5 × 10<sup>-12</sup> has been reported by Cooper et al.<sup>1</sup> The value of the rate constants recommended here differ only slightly from those of Luther et al., (who report k<sub>∞</sub><sup>300</sup> = 5.2 × 10<sup>-12</sup>; m = 1.4 and k<sub>0</sub><sup>300</sup> = 1.5 × 10<sup>-30</sup>; n = -6.3; F<sub>c</sub> = 0.35 × (T/300)<sup>-0.35</sup> using the IUPAC formula) but yield an overall rate constant within their error limits.

**F16.  $\text{CFCl}_2 + \text{O}_2$ .** Values for both low- and high-pressure limits at 300 K are from Caralp and Lesclaux.<sup>1</sup> Forst and Caralp<sup>2</sup> have examined this reaction theoretically. Temperature dependences are rough estimates based on their calculations and by analogy with similar reactions.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Caralp, F.; Lesclaux, R. Rate constant for the reaction of the  $\text{CFCl}_2$  radical with oxygen in the pressure range 0.2-12 Torr at 298 K. *Chem. Phys. Lett.* **1983**, *102*, 54-58.
- (2) Forst, W., and F. Caralp Microcanonical variational theory of radical recombination by inversion of interpolate partition function Part 2.- $\text{CX}_3 + \text{O}_2$  (X = H, F, Cl). *J. Chem. Soc. Faraday Trans.* **1991**, *87*, 2307-2315.

**F17.  $\text{CF}_2\text{Cl} + \text{O}_2$ .** The recommended  $k_0(300)$  and  $k_\infty(300)$  are from the experimental work reported by Codnia and Azcárate,<sup>1</sup> and the recommended temperature exponents are taken from the theoretical predictions of Forst and Caralp.<sup>2</sup> Codnia and Azcárate used  $\text{CO}_2$  laser IR multiphoton dissociation of  $\text{CF}_2\text{Cl}_2$  to prepare  $\text{CF}_2\text{Cl}$  radicals in the presence of  $\text{O}_2$  (and  $\text{N}_2$  buffer gas) at 300 K. Subsequent fast reactions produced vibrationally excited  $\text{CF}_2\text{O}^*$ , which they monitored by measuring its spontaneous IR fluorescence near  $1928 \text{ cm}^{-1}$ . They showed that the growth and decay rates of the IR fluorescence intensity are due to the reactions of  $\text{CF}_2\text{Cl}$  radicals with  $\text{O}_2$  and to the rate of collisional deactivation of  $\text{CF}_2\text{O}^*$ . Analysis of the reaction rates between  $\text{CF}_2\text{Cl}$  and  $\text{O}_2$  revealed the existence of both the pressure-dependent recombination reaction and a direct bimolecular step (previously proposed by other workers; see Table 1-1) are important in the pressure range from 0 to 20 mbar of  $\text{N}_2$ . Separate control of  $\text{O}_2$  concentrations enabled them to obtain the rate constant for the direct reaction (Table 1-1), as well as  $k_0(300)$  and  $k_\infty(300)$  for the recombination. The latter values are in rough agreement with the theoretical predictions of Forst and Caralp,<sup>2</sup> who predicted temperature exponents in approximate agreement with similar reactions. The estimated errors are relatively large because the reaction has been measured only once at 300 K and because the temperature dependence is based on theoretical predictions.

**G1. Br + NO<sub>2</sub>.** The recommended values are from a study by Kreutter et al.<sup>2</sup> They regarded the product as  $\text{BrNO}_2$ . Their  $k_o$  value in He agrees with the measurement of Mellouki et al.<sup>4</sup> at 300 K. Broske and Zabel<sup>1</sup> and Orlando and Burkholder<sup>5</sup> have shown that *cis*-BrONO is the major product in their studies. Orlando and Burkholder<sup>5</sup> suggest that isomerization to  $\text{BrNO}_2$  is heterogeneous. Lee<sup>3</sup> calculated structure, frequencies and energetics for  $\text{BrNO}_2$ , *cis*-BrONO and *trans*-BrONO. A Patrick-and-Golden-type calculation using the Lee<sup>3</sup> results yields  $k_o$ (strong collision)  $\approx 1.2, 2.5$ , and  $2.1$  in units of  $1 \times 10^{-31} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$  for *trans*-BrONO, *cis*-BrONO, and  $\text{BrNO}_2$ , respectively. The sum,  $5.9 \times 10^{-31}$ , multiplied by a collision efficiency in  $\text{N}_2$  of 0.3 is a factor of about 2.5 lower than the observed  $k_o$  value. Also, the relative yield of  $\text{BrNO}_2$  is somewhat too high since Orlando and Burkholder<sup>5</sup> measure  $\text{BrONO} > 75\%$ . Kreutter et al.<sup>2</sup> report an equilibrium constant, which, if *cis*-BrONO is assumed to be the product, suggests bond strengths for the BrONO compounds that are about 4 kcal mole<sup>-1</sup> higher than the Lee<sup>3</sup> calculation. Computing  $k_o$  with these new values yields  $k_o \approx 4.5$  and  $6.4$  in units of  $1 \times 10^{-31}$  for *trans*-BrONO and *cis*-BrONO, respectively. When the sum of the rate constants for the three channels is multiplied by the collision efficiency (0.3), the result is  $3.9 \times 10^{-31}$  and the yield of BrONO is 85%.

- (5) Orlando, J. J.; Burkholder, J. B. Identification of BrONO as the major product in the gas-phase reaction of Br with  $\text{NO}_2$ . *J. Phys. Chem. A* **2000**, *104*, 2048-2053, doi:10.1021/jp993713g.

**G2. BrO + NO<sub>2</sub>.** Recommended values are from a global least squares fit of data from Thorn et al.<sup>10</sup> and Sander et al.<sup>9</sup>, which are in excellent agreement at 298 K. The recommended values differ only slightly from the previous recommendation. Danis et al.<sup>1</sup> give slightly lower values for the low-pressure-limiting rate constant and a smaller temperature dependence as well. This latter study may be hampered by heterogeneous effects, but can be accommodated within the error limits recommended. A theoretical study by Rayez and Destriau<sup>8</sup> suggests that the bond-dissociation energy in  $\text{BrONO}_2$  is 8.5 kcal mol<sup>-1</sup> higher than in  $\text{ClONO}_2$ , thus rationalizing the relative values of the low-pressure-limiting rate constants for these two processes. A more detailed theoretical study by Parthiban and Lee,<sup>6</sup> as well as a study by Orlando and Tyndall,<sup>5</sup> who measured  $\text{BrONO}_2$  decomposition and thus an equilibrium constant, both determine only 1.6 kcal mol<sup>-1</sup> for the above difference. A theoretical study by Zou et al.<sup>12</sup> agrees with the latter figure. A Patrick and Golden<sup>7</sup> type calculation, even with the stronger bond of Rayez and Destriau<sup>8</sup> yields a value for the low pressure limiting rate constant that is smaller than observed. Lessar et al.<sup>4</sup> calculate a potential energy surface for BrONO. They find that the  $\text{BrO}-\text{ONO}$  bond strength is of the order of 7 kcal mol<sup>-1</sup>, which is too weak to have any effect on the overall rate of  $\text{BrO} + \text{NO}_2$ . Walsh and Golden<sup>2,11</sup> have attempted to fit the data with a master equation analysis and found that the usual energy transfer treatment at low pressures is insufficient to fit the data (this was probably due to a bug that was found in that version of the master equation code). Kreycy et al.<sup>3</sup>

analyzed atmospheric data and concluded that the recombination rate constant needed to fit the data near 200 K is smaller than the (previous) recommendation.

**G3. Br + CH<sub>2</sub>=CHCH=CH<sub>2</sub> (1,3-butadiene).** In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF<sub>2</sub>Br<sub>2</sub> precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.<sup>2</sup> determined the recombination rate constant from 227 to 298 K. The products are thought to consist of two isomers, but they were not identified in the experiments. Calculations (G4 method) reported by Laine et al. show that addition of Br to a terminal carbon atom is thermodynamically favored. The rate constants reported by Laine et al.<sup>2</sup> are about 2× as large as relative measurements at 298 K and 1 bar reported previously by Bierbach et al.<sup>1</sup> Bierbach et al. placed their rate constant on an absolute basis by employing a linked chain of relative rate measurements, which consisted of reactions of Br with 2,3-dimethyl-2-butene, trans-2-butene, propene, and terminated with an absolute rate constant for Br + acetaldehyde; thus the uncertainties may have accumulated. The current recommendation is based on the parameters measured in the direct experiments of Laine et al.<sup>2</sup> The recommended 2σ error bars encompass all of the data of Laine et al.

**G4. Br + CH<sub>2</sub>=C(CH<sub>3</sub>)CH=CH<sub>2</sub> (isoprene).** In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF<sub>2</sub>Br<sub>2</sub> precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.<sup>2</sup> determined the rate constant from 227 to 298 K. The products may consist of several isomers; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is BrH<sub>2</sub>CC(CH<sub>3</sub>)CH=CH<sub>2</sub>, but the identities of the isomers actually produced in the reaction are not known. Laine et al. also measured the rate constants for the reaction of Iso-Br + O<sub>2</sub> (see Table 1-1) and for the reaction of Br + 1,3-butadiene in both the presence and absence of O<sub>2</sub>. They found that the apparent rate of the latter reaction is affected by the presence of O<sub>2</sub>. Bierbach et al.<sup>1</sup> previously reported relative rate constants at 298 K and 1 bar of air. They placed their rate constants on an absolute basis by employing a linked chain of five relative rate measurements, consisting of reactions of Br with 1,3-butadiene, 2,3-dimethyl-2-butene, trans-2-butene, propene, and terminated with an absolute rate constant for Br +

acetaldehyde; thus the uncertainties may have accumulated. The current recommendation is based on the parameters measured in the direct experiments of Laine et al.<sup>2</sup> in the absence of O<sub>2</sub>. The recommended 2σ error bars encompass all of the data of Laine et al.

**H2.** **I + NO<sub>2</sub>.** Evaluation taken from IUPAC.<sup>2</sup> The data are from van den Bergh et al.,<sup>5</sup> Mellouki et al.,<sup>3</sup> Buben et al.,<sup>1</sup> and van den Bergh and Troe.<sup>6</sup> IUPAC uses F<sub>c</sub> = 0.63, which is essentially the same as the universal value adopted here of F<sub>c</sub> = 0.6. (No evidence of possible isomers [INO<sub>2</sub> or IONO] is reported.) Error limits transposed to the current format. Tucceri et al.<sup>4</sup> used laser flash photolysis coupled to resonance-fluorescence detection of I atoms to measure the rate coefficients for the reaction: I + NO<sub>2</sub> + M → INO<sub>2</sub> + M. Rate coefficients at 298 K when combined with other datasets obtained at higher and lower pressures, were adequately described by a simplified Troe function with the parameters: k<sub>0</sub>(He, 330 K) = 1.48 × 10<sup>-31</sup> cm<sup>6</sup> molecule<sup>-2</sup> s<sup>-1</sup>, F<sub>c</sub>(He) = 0.43, and k<sub>∞</sub> = 1.1 × 10<sup>-10</sup> cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> for He as bath gas. In N<sub>2</sub> (or air) the following parameters were obtained k<sub>0</sub>(N<sub>2</sub>, 300 K) = 3.2 × 10<sup>-31</sup> cm<sup>6</sup> molecule<sup>-2</sup> s<sup>-1</sup>, F<sub>c</sub>(N<sub>2</sub>) = 0.48, with k<sub>∞</sub> = 1.1 × 10<sup>-10</sup> cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>. These parameters essentially reproduce the values at 300 K from the parameters in the Table.

**H3.** **IO + NO<sub>2</sub>.** Data from Daykin and Wine,<sup>2</sup> Hölscher and Zellner,<sup>5</sup> Allan and Plane,<sup>1</sup> Jenkin and Cox,<sup>6</sup> and Dillon et al.<sup>3</sup> are considered. Dillon et al. suggest that the value from Hölscher and Zellner might be low at 298 K due to regeneration of IO, although their values at lower temperatures are in agreement with others. The recommendation takes this into consideration and accommodates the rest of the data. Two more studies at lower pressures are available, Larin et al.<sup>8</sup> and Maguin et al.<sup>9</sup> These latter do not agree very well with the above five studies and have larger experimental errors. The recommended k<sub>o</sub> and k<sub>∞</sub> also agree with a theoretical study by Rayez and Destriau.<sup>12</sup> A computational study by Marshall<sup>10</sup> sets the bond dissociation energy as ΔH<sub>0</sub>(IO-NO<sub>2</sub>) = 113.6 ± 3.1 kJ mol<sup>-1</sup> and suggests k<sub>o</sub> = (5.3–13.3) × 10<sup>-31</sup> cm<sup>6</sup> molecule<sup>-1</sup> s<sup>-1</sup> for N<sub>2</sub> as the bath gas, while an ME/RRKM study by Golden<sup>4</sup> required ΔH<sub>0</sub>(IO-NO<sub>2</sub>) ~150 kJ mol<sup>-1</sup> to fit the data. Papayannis and Kosmas<sup>11</sup> compute ΔH<sub>0</sub>(IO-NO<sub>2</sub>) = 137.6 or 131.7 kJ mol<sup>-1</sup>, depending on spin orbit coupling corrections in IO. A computational study by Koltsoyannis and Plane<sup>7</sup> concludes that ΔH<sub>0</sub>(IO-NO<sub>2</sub>) = 117.9 kJ mol<sup>-1</sup>. See Table 3-1 for the recommended K<sub>eq</sub>. - II. HS + NO.** Data are from the work of Black et al.<sup>1</sup> The temperature dependence of k<sub>∞</sub> has been estimated and k<sub>0</sub> has been adjusted to fit the data.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Black, G.; Patrick, R.; Jusinski, L. E.; Slanger, T. G. Rate coefficients for the reaction  $\text{HS} + \text{NO} + \text{M}$  ( $\text{M} = \text{He}$ ,  $\text{Ar}$ , and  $\text{N}_2$ ) over the temperature range 250- 445 K. *J. Chem. Phys.* **1984**, *80*, 4065-4070.
- I2.**  **$\text{CH}_3\text{S} + \text{NO}$ .** The recommended values are fit to the study by Balla et al.<sup>1</sup> The temperature range was 295 to 453 K and pressures of  $\text{N}_2$  from 1.5 to 300 Torr. The recommended high pressure limiting rate coefficient and temperature dependence provide a better fit to the data than reported by Balla et al.  
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kinetics of the reaction of  $\text{CH}_3\text{S}$  with  $\text{NO}$ ,  $\text{NO}_2$  and  $\text{O}_2$ . *Chem. Phys.* **1986**, *109*, 101-107.
- I3.**  **$\text{O} + \text{SO}_2$ .** Naidoo et al.<sup>4</sup> studied this spin-forbidden reaction in Ar over the temperature range  $290 < T/\text{K} < 840$  and pressure range  $100 < P/\text{mbar} < 880$ . They fit the data very well using the IUPAC<sup>1</sup> format with  $k_0 = 9.5 \times 10^{-23} \text{ T}^{-3} \exp(-2400/T) \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ ,  $k_\infty = 6.1 \times 10^{-13} \exp(-850/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  and  $F_c = 0.558 \exp(-T/316) + 0.442 \exp(-T/7442)$ . The recommended values transpose the rate constants to the form used in this evaluation and are used with the standard value of  $F_c = 0.6$ . These parameters do not fit the higher temperatures as well as the values derived by Naidoo et al. (i.e. missing the values at 840 K by about 50% and those at 699 K by about 20%), but values at 289, 399 and 581 K are fit quite well and are adequate for atmospheric conditions. Earlier values are reported by Atkinson and Pitts<sup>2</sup> and Müller et al.<sup>3</sup>

- I4.**  **$\text{OH} + \text{SO}_2$ .** Values of the rate constant as a function of pressure and temperature are from Blitz et al.<sup>4</sup> They used a five parameter fit to the data, allowing  $F_c$  to be temperature dependent. The values of  $k_0$  and  $k_\infty$  have been adjusted in the Table to accommodate  $F_c = 0.6$ . Blitz et al.<sup>4</sup> determined the high pressure limit from the reaction of  $\text{OH}(v=1)$  with  $\text{SO}_2$ . Their low pressure value was taken by re-evaluating the data of Wine et al.<sup>9</sup> in various bath gases at pressures up to 150 Torr and temperatures between 260 K and 420 K, through the use of a master equation. The data of Paraskevopoulos et al.<sup>8</sup> in the same pressure range, are equally well fit. Lower pressure data from at 298 K from Leu<sup>6</sup> and Lee et al.<sup>5</sup> are well accommodated by the recommendation herein. Earlier data listed in Baulch et al.,<sup>3</sup> Baulch et al.,<sup>2</sup> and Atkinson et al.<sup>1</sup> are noted. Blitz et al.<sup>4</sup> have calculated the entropy and measured a third law heat of formation for  $\text{HOSO}_2$  ( $373 \pm 6 \text{ kJ/mol}$ ). See also Li and McKee.<sup>7</sup>

**I5.  $\text{CH}_3\text{S} + \text{O}_2$ .** The Panel makes no recommendation, since only one direct measurement of the rate constant has been reported and helium bath gas is not appropriate for the atmosphere. The following is for information, only.

Turnipseed et al.<sup>4</sup> generated  $\text{CH}_3\text{S}$  radicals by pulsed laser photolysis of  $\text{CH}_3\text{SCH}_3$  with  $\text{O}_2$  in excess and used LIF of  $\text{CH}_3\text{S}$  to monitor the subsequent reaction. Biexponential decays were observed, signaling the reversible formation of a weakly bound complex. They obtained forward and reverse rate constants in 80 Torr of He bath gas at temperatures from 216 to 250 K; the values of  $K_{\text{eq}} = k_{\text{rec}}/k_{\text{uni}}$  are in good agreement with the recommended  $K_{\text{eq}}$  (see Table 3-1). Assuming that  $k_{\text{rec}}$  is near the low pressure limit, the data of Turnipseed et al. are described by  $k_0(T) = 8 \times 10^{-32} (\text{T}/298)^{-5.7}$  in helium bath gas. The reaction has been implicated in three indirect studies,<sup>1-3</sup> which reported estimated ratios of rate constants.

Phys. Chem.* **1993**, 97, 8442-8449.

**I7.  $\text{SO}_3 + \text{NH}_3$ .** Recommendation is from Lovejoy.<sup>1</sup> This study covered 20–80 Torr from 280–340 K. An earlier study by Lovejoy and Hanson,<sup>2</sup> who studied this reaction from 10–400 Torr  $\text{N}_2$  at 295 K is in agreement. Lovejoy and Hanson<sup>2</sup> observed that any incipient adduct rapidly becomes sulfamic acid ( $\text{H}_3\text{NSO}_3$ ) which clusters efficiently with itself and sulfuric acid. The observed sulfamic acid dimerization rate constant exceeds  $5 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ . Measurements of Shen et al.<sup>3</sup> at 1–2 Torr He are much higher than those of Lovejoy and Hanson<sup>2</sup> or Lovejoy.<sup>1</sup> Error limits have been adjusted to take into account the fact that the exponent of the temperature dependence of the low pressure rate constant is unusually large. Lovejoy<sup>1</sup> also reports an equilibrium constant and heat of formation of sulfamic acid of  $-24 \pm 1$  kcal mol<sup>-1</sup>.

**I8.  $\text{HO} + \text{CS}_2$ .** The data are from Hynes et al.<sup>3</sup> and Murrells et al.<sup>4</sup> The value  $m = 1$  is constrained. The recommended rate constant is in reasonable agreement with the measurement of Bulatov et al.<sup>1</sup> Petris et al.<sup>2</sup> report experimental detection of  $\text{CS}_2\text{OH}$ . See Table 3-1 for the recommended equilibrium constant. The adduct reacts slowly with  $\text{O}_2$ . (See Table 1-1).

**I9. Cl + CS<sub>2</sub>.** The data are from Nicovich et al.<sup>2</sup> Wallington et al.<sup>3</sup> have also studied this system. The value m = 0 is constrained. Nicovich et al.<sup>2</sup> confirm that the reaction proceeds via reversible adduct formation as suggested by Martin et al.<sup>1</sup> The much larger rate constant values determined by Martin et al. may possibly be attributed to reactive impurities in the CS<sub>2</sub> sample. Nicovich et al. set an upper limit on the rate constant for the adduct (CS<sub>2</sub>Cl) reacting with O<sub>2</sub> of  $2.5 \times 10^{-16}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> at room temperature. Wang and Phillips<sup>4</sup> have reported a theoretical study of the adduct.

**I10. OH + CH<sub>3</sub>SCH<sub>3</sub> → (CH<sub>3</sub>)<sub>2</sub>SOH → products.** The OH + CH<sub>3</sub>SCH<sub>3</sub> reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the direct reaction is discussed separately in Table 1-1. The product of the reversible addition pathway reacts with O<sub>2</sub> creating an irreversible path as well. Mechanistically, this pathway is described by combining the rate constants k<sub>f</sub> for the addition step, k<sub>r</sub> for the reverse dissociation step, and k<sub>O<sub>2</sub></sub> for the adduct reaction with O<sub>2</sub>. This is discussed in detail in the notes for Table 1-1. The equilibrium constant for the reversible addition process is K<sub>c</sub> = k<sub>f</sub>/k<sub>r</sub>. Recommendations for K<sub>c</sub>, and k<sub>O<sub>2</sub></sub> are found in Tables 3-1, and 1-1, respectively. The value for k<sub>f</sub> recommended here is from Williams et al.<sup>1</sup> The discussion in Table 1-1 points out that this value taken with K<sub>c</sub> and k<sub>O<sub>2</sub></sub> fits the extant data very well.

(Table: 10-6; Note: 10-6; Evaluated: 10-6) [Back to Table](#)

- (1) Williams, M. B.; Campuzano-Jost, P.; Hynes, A. J.; Pounds, A. J. Experimental and theoretical studies of the reaction of the OH radical with alkyl sulfides: 3. Phys. Chem. A* **2009**, *113*, 6697-6709, doi:10.1021/Jp9010668.

**I11. Cl + (CH<sub>3</sub>)<sub>2</sub>S.** [See Table 1-1] If the HCl yield at 297 K from Stickel et al.<sup>4</sup> is used as a measure of the abstraction reaction, the rate constant would be  $1.64 \times 10^{-10}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>. Using this value the complete data set from Stickel et al.<sup>4</sup> can be fit with the form used in Table 2-1 with the addition of a term for the abstraction in the form k<sub>abs</sub> =  $1.64 \times 10^{-10}(T/300)^a$ . The value of “a” obtained in this manner is almost zero, so the data are fit with: k<sub>0</sub> =  $4 \times 10^{-28}(T/300)^{-7.0}$  and k<sub>∞</sub> =  $2 \times 10^{-10}(T/300)^{-1}$  along with the temperature independent value of k<sub>abs</sub>. These parameters are recommended herein. Enami et al.<sup>2</sup> propose k<sub>0</sub> =  $2.2 \times 10^{-28}$  and k<sub>∞</sub> =  $2.2 \times 10^{-10}$  at 298 K along with k<sub>abs</sub> =  $1.8 \times 10^{-10}$ . On the other hand, a study by Diaz-de-Mera et al.<sup>1</sup> performed in the temperature range 259 < T/K < 364 and in helium at pressures of 0.5 < P/Torr < 1 reports a value k<sub>abs</sub> =  $(2.0 \pm 1.2) \times 10^{-10} \exp[-(332 \pm 173)/T]$ , which yields  $6.6 \times 10^{-11}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> at room temperature. Several studies, both experimental by Urbanski and Wine<sup>5</sup> and theoretical by Resende and De Almeida<sup>3</sup> make it clear that at higher pressures an adduct Cl-S(CH<sub>3</sub>)<sub>2</sub> is formed and this adduct does not yield CH<sub>3</sub> radicals or the products of the abstraction pathway.

**I12. Br + (CH<sub>3</sub>)<sub>2</sub>S.** Wine et al.<sup>5</sup> data for the adduct formation in N<sub>2</sub> at 25 < P/Torr < 600 and 263 < T/K < 310 are the basis for the recommendation. Studies by Ingham et al.<sup>2</sup> and Nakano et al.<sup>4</sup> are in agreement. Nakano et al.<sup>4</sup> is also in agreement with the value of the equilibrium constant. However, Maurer et al.<sup>3</sup> find a value at 300 K and 1 bar total pressure of a mixture of 5% O<sub>2</sub> and 95% N<sub>2</sub>, only 2% as high as the value computed from the recommended parameters. This latter value is supported by Ballesteros et al.<sup>1</sup>

**J1. Na + O<sub>2</sub>.** A study by Plane and Rajasekhar<sup>3</sup> finds k<sub>o</sub> = (2.9 ± 0.7) × 10<sup>-30</sup> cm<sup>6</sup> molecule<sup>-2</sup> s<sup>-1</sup> at 300 K with n = 1.30 ± 0.04. They also estimate k<sub>∞</sub> to be about 6 × 10<sup>-10</sup> cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> with a small positive temperature dependence. Another study by Helmer and Plane<sup>1</sup> yields k<sub>o</sub> = (3.1 ± 0.2) × 10<sup>-30</sup> cm<sup>6</sup> molecule<sup>-2</sup> s<sup>-1</sup> at 300 K with n = 1.52 ± 0.27. The recommended values are taken from these studies. They are consistent with values measured by Marshall et al.<sup>2</sup> at 600 K and those measured by Vinckier et al.<sup>5</sup> at higher temperature. The k<sub>o</sub> value is about 60% higher than that of Silver et al.<sup>4</sup>

- J5. Hg + Br.** The recommendation is based on the direct experiments of Donohoue et al.,<sup>2</sup> who used pulsed laser photolysis of Br<sub>2</sub> to generate an excess of Br atoms, which reacted with Hg<sup>0</sup> vapor; the Hg<sup>0</sup> and atomic Br were monitored simultaneously by pulsed laser induced fluorescence techniques. The recombination reaction rate constant at the low pressure limit was measured in N<sub>2</sub> gas at temperatures from 243 to 293 K and N<sub>2</sub> pressures from 200 to 600 Torr (measurements were also carried out using He gas). In earlier studies, Greig et al.<sup>5</sup> analyzed the UV spectrum of HgBr and used their measured absorption coefficients to determine the recombination rate constant from 393 K to 448 K in 200 Torr of CF<sub>3</sub>Br (conditions not relevant to the atmosphere). Ariya et al.<sup>8</sup> and Spicer et al.<sup>9</sup> used relative rate techniques to obtain the rate constant, but both studies are discussed in detail by Donohoue et al.,<sup>2</sup> who concluded that they were seriously affected by secondary reactions. Several theoretical calculations have been reported.<sup>3,4,6,7</sup> In particular, Goodsite et al.<sup>3</sup> used spectroscopic data, quantum chemistry calculations, and RRKM modeling to show that the theoretical results are in reasonable agreement with experiments. Later, using a corrected bond dissociation energy, they repeated the calculations<sup>4</sup> and showed that with a reasonable choice of an energy transfer parameter, the RRKM results are in very good agreement with the experiments of Donohoue et al.<sup>2</sup> A review of Hg atmospheric chemistry has appeared.<sup>1</sup> (Table: 15-10; Note: 15-10; Evaluated: 15-10) [Back to Table](#)

3.2 Definitions.....	3-1
3.3 Notes to Table 3-1.....	3-5
3.4 Bibliography – Equilibrium Constants .....	3-19

### Tables

TABLE 3-1. EQUILIBRIUM CONSTANTS .....	3-3
--	-----

#### 3.1 Format

Some of the three-body reactions in Table 2 form products that are thermally unstable at atmospheric temperatures. In such cases the thermal decomposition reaction may compete with other loss processes, such as photodissociation or radical attack. Table 3 lists the equilibrium constants,  $K_{eq}$  (T), for several reactions that may fall into this category. The table has three column entries, the first two being the parameters A and B that can be used to express  $K_{eq}$  (T):

$$K_{eq} \text{ (T)/cm}^3 \text{ molecule}^{-1} = A \exp(B/T) \quad (200 < T < 300 \text{ K})$$

The third column entry in Table 3 is the calculated value of  $K_{eq}$  at 298 K.

The data sources for  $K_{eq}$  (T) are described in the individual notes to Table 3.

#### 3.2 Definitions

When values of the heats of formation and entropies of all species are known at the temperature T, we note that the equilibrium constant is given by the van't Hoff equation:

$$\log_{10} \left[ K_{eq}(T) / \text{bar}^{-1} \right] = \frac{\Delta S_T^\circ}{2.303R} - \frac{\Delta H_T^\circ}{2.303RT}$$

$$\log_{10} \left[ K_{eq}(T) / \text{cm}^3 \text{ molecule}^{-1} \right] = \frac{\Delta S_T^\circ}{2.303R} - \frac{\Delta H_T^\circ}{2.303RT} + \log_{10}(T) - 21.87$$

where the superscript “o” refers to a standard state of one bar. When the entropy is known (or can be calculated from molecular properties) as a function of temperature, experimental values of  $K_{eq}(T)$  can be used to extract a value for  $\Delta H_0$  and  $K_{eq}(T)$  can be calculated over a wide temperature range (Third law method.). The parameters A and B can then be determined from a linear fit. In other cases the  $K_{eq}(T)$  values were calculated directly from kinetic data for the forward and reverse reactions. When only thermochemical values at 298 K were available, they were treated as temperature independent and used to calculate the equilibrium constants between 200 and 300 K. The following equations were then used to calculate the parameters A and B:

$$B/K = 2.303 \left[ \frac{(300 \times 200)}{(300 - 200)} \right] \log_{10} \left( \frac{K_{eq}^{200}}{K_{eq}^{300}} \right) = 1382 \log_{10} \left( \frac{K_{eq}^{200}}{K_{eq}^{300}} \right)$$

$$\log_{10}(A) = \log_{10}(K_{eq}^T) - \frac{B}{2.303T}$$

The relationships between the parameters A and B and the quantities  $\Delta S^\circ(298 \text{ K})$  and  $\Delta H^\circ(298 \text{ K})$  are:

$$A = \frac{eR'T}{N_{av}} \exp\left(\frac{\Delta S^0_{298K}}{R}\right) = 3.7 \times 10^{-22} T \exp\left(\frac{\Delta S^0_{298K}}{R}\right)$$

where  $R' = 82.1 \text{ cm}^3 \text{ bar mole}^{-1} \text{ K}^{-1}$ , and  $N_{av} = 6.02 \times 10^{23} \text{ molecule mole}^{-1}$  and

$$B^{\circ} K = - \left[ \frac{\Delta H^0_{298K} + RT}{R} \right]$$

$$K_{eq}/\text{cm}^3 \text{molecule}^{-1} = A \exp(B/T) [200 < T/\text{K} < 300]$$

Shaded areas indicate changes or additions since 10-6.

a f(298 K) is the uncertainty factor at 298 K, and g is a measure of the uncertainty in the quantity B. To calculate the uncertainty at temperatures other than 298 K, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left( \frac{1}{T} - \frac{1}{298} \right) \right|$$

### 3.3 Notes to Table 3-1

JPL Publication numbers for the most recent revision of the table entry, note and evaluation date are given at the end of each note.

1.  $\text{H}_2\text{O} + \text{H}_2\text{O} \rightarrow (\text{H}_2\text{O})_2$  (**water dimer**). The recommendation is based on the optimized Active Thermochemical Tables of Ruscic,<sup>1</sup> which utilizes a comprehensive thermochemical network that includes all of the prior work related to this equilibrium.  $K_{\text{eq}}$  from Ruscic agrees very well with the recent work of Scribano et al.<sup>2</sup> and references cited therein. The error limit was set to encompass the exponential fit to the  $K_{\text{eq}}$  of Ruscic (which is not exactly exponential). For more accurate values, the following non-exponential fit falls within 2% of Ruscic's values:

$$K_{\text{eq}} = 1.92 \times 10^{-23} \exp[(1 + 43/T)*1216/T] \text{ cm}^3 \text{ molecule}^{-1}$$

(Table: 15-10; Note: 15-10; Evaluation 15-10) [Back to Table](#)

- (1) Ruscic, B. Active thermochemical tables: Water and water dimer. *J. Phys. Chem. A* **2013**, *117*, 11940-11953, doi:10.1021/jp403197t.  
(2) Scribano, Y.; Goldman, N.; Saykally, R. J.; Leforestier, C. Water dimers in the atmosphere III: Equilibrium constant from a flexible potential. *J. Phys. Chem. A* **2006**, *110*, 5411-5419, doi:10.1021/jp056759k.

2.  $\text{HO} + \text{NO}_2 \rightarrow \text{HOONO}$ . The tabulated value is for the *cis,cis*-HOONO product channel (see below for formation of the *trans,perp*-HOONO isomer, which is unlikely to be important in the atmosphere). Using the data from Hippler et al.,<sup>4</sup> Golden et al.<sup>2,3</sup> performed a third law analysis using structures and frequencies from an ab initio quantum calculation to extract the heat of formation of *cis-cis*-HOONO ( $\Delta H_f^\circ(0 \text{ K}) = -9.3 \text{ kJ mol}^{-1}$ ). The data covers  $430 < T/\text{K} < 475$  with 30% uncertainties. Most vibrational frequencies recently have been identified using matrix isolation spectroscopy<sup>10</sup> and the moments of inertia have been measured by microwave spectroscopy.<sup>1</sup> High level CCSD(T) calculations and spectral simulation of overtone and action spectra have examined the torsion in considerable detail.<sup>9</sup> Mathews and Sinha<sup>8</sup> measured overtone action spectra and carried out an analysis that gave  $D_0 = 83.3 \pm 2.1 \text{ kJ mol}^{-1}$ . By using the observed frequencies (supplemented by the high level CCSD(T) calculations<sup>10</sup>), moments of inertia, and the potential energy and moment of inertia of the internal rotor,<sup>9</sup> a new third law analysis using the data from Hippler et al.<sup>4</sup> gives the entropy for reaction that differs from the previous analysis by  $-5.6 \text{ J K}^{-1} \text{ mol}^{-1}$  and a new estimate of  $D_0 = 81.5 \pm 0.8 \text{ kJ mol}^{-1}$  and  $\Delta H_f^\circ(0 \text{ K}) = -7.6 \text{ kJ mol}^{-1}$  ( $\Delta H_f^\circ(298 \text{ K}) = -14.9 \text{ kJ mol}^{-1}$  and  $S_f^\circ(298) = 279 \text{ J K}^{-1} \text{ mol}^{-1}$ ).

For formation of the *trans,perp*-HOONO product channel (which is of negligible atmospheric importance), the reaction is written  $\text{HO} + \text{NO}_2 \rightarrow \text{trans,perp-HOONO}$ . Konen et al.<sup>5,6</sup> used infrared overtone action spectroscopy in a molecular beam apparatus to determine  $D_0 = 67.8 \pm 0.4 \text{ kJ mol}^{-1}$ . High level CCSD(T) calculations<sup>5</sup> supported by analysis<sup>7</sup> of the action spectra give vibrational frequencies and moments of inertia. These data are used to calculate  $\Delta H_f^\circ(0 \text{ K}) = 6.1 \text{ kJ mol}^{-1}$  ( $\Delta H_f^\circ(298 \text{ K}) = -0.5 \text{ kJ mol}^{-1}$  and  $S_f^\circ(298) = 291 \text{ J K}^{-1} \text{ mol}^{-1}$ ). Using these parameters, the equilibrium constant is given by  $K_{\text{eq}}(\text{trans,perp}) = 1.33 \times 10^{-26} \exp(8390/T)$  with uncertainty factors set so that all of the data used for the recommendation fall within the  $2\sigma$  error bounds.

**3.  $\text{HO}_2 + \text{NO}_2$ .** The value was obtained by combining the expression from Table 2-1 for the rate constant of the reaction as written with that from an average of the expressions from Graham et al.<sup>3</sup> and Zabel<sup>4</sup> for the reverse reaction. Values for the entropy and heat of formation of pernitric acid may be extracted. These values are:  $S(298 \text{ K}) = 71.7 \text{ cal mole}^{-1} \text{ K}^{-1}$  and  $\Delta H_f(298 \text{ K}) = -12.9 \text{ kcal mole}^{-1}$ . If the entropy is calculated from the frequencies and moments of inertia given by Chen and Hamilton,<sup>1</sup> the value becomes 71.0 and the heat is -13.1. The values in the Thermochemistry Section of this report reflect these results. A study of the thermal decomposition of  $\text{HO}_2\text{NO}_2$  by Gierczak et al.<sup>2</sup> combined with values for the association reaction are in agreement.

**4.  $\text{HO}_2 + \text{H}_2\text{O}$ .** The influence of water vapor on the  $\text{HO}_2 + \text{HO}_2$  bimolecular rate constant was first shown by Hamilton,<sup>3</sup> who invoked formation of a  $\text{HO}_2\bullet\text{H}_2\text{O}$  complex with  $\sim 38 \text{ kJ mol}^{-1}$  binding energy. Since then, several other groups have quantified the effect on the  $\text{HO}_2 + \text{HO}_2$  reaction (see Table 1). Only two direct measurements of the equilibrium constant have been carried out. Aloisio et al.<sup>1</sup> used FTIR absorption spectroscopy around  $1120 \text{ cm}^{-1}$  to measure the depletion of gas phase  $\text{HO}_2$  as it formed a complex with  $\text{H}_2\text{O}$ . They measured  $K_{\text{eq}}$  at 230 and 250 K, but only an upper limit at room temperature. Kanno et al.<sup>5,6</sup> also monitored depletion of gas-phase  $\text{HO}_2$ , but with high resolution FM spectroscopy of the  $\text{HO}_2$  A-X transition near  $7020 \text{ cm}^{-1}$  with apparently higher sensitivity than in the FTIR measurement of Aloisio et al., since they could measure  $K_{\text{eq}}$  up to much higher temperatures ( $250 \text{ K} \leq T \leq 350 \text{ K}$ ). The two studies are in rough agreement on parameter B, but differ on parameter A by a factor of 7. Kanno et al.'s results are in very good agreement with the Aloisio et al. ab initio calculations of parameter A. The indirect estimate of  $K_{\text{eq}}$  by Cox and Burrows<sup>2</sup> agrees better with Kanno et al., and the indirect estimate by Hamilton and Lii<sup>4</sup> is in better agreement with Aloisio et al. The current recommendation for  $K_{\text{eq}}$  is based on Kanno et al.<sup>5,6</sup> because their technique had higher sensitivity and because they measured  $K_{\text{eq}}$  over a much wider temperature range. A 3rd Law analysis of the Kanno et al. experimental data was carried out using the harmonic frequencies calculated by Aloisio et al.<sup>1</sup> and the microwave rotational constants from Suma et al.<sup>7</sup> This gives  $S^{\circ}_{298}(\text{HO}_2\bullet\text{H}_2\text{O}) = 308.9 \text{ J K}^{-1} \text{ mol}^{-1}$  and  $D_0 = 35.9 \pm 1.2 \text{ kJ mol}^{-1}$  (one sigma). Since the analysis is based only on the Kanno experiments, we adopt an estimated 95% confidence limit of  $\pm 3 \text{ kJ mol}^{-1}$ . The results give  $\Delta H_{f,0}(\text{HO}_2\bullet\text{H}_2\text{O}) = -259.6 \pm 3 \text{ kJ mol}^{-1}$  and  $\Delta H_{f,298}(\text{HO}_2\bullet\text{H}_2\text{O}) = -268.0 \pm 3 \text{ kJ mol}^{-1}$ . The values of f(298) and g were made large enough to include the data of Aloisio et al.<sup>1</sup>

**5. HO<sub>2</sub> + CH<sub>3</sub>OH.** The influence of CH<sub>3</sub>OH on the HO<sub>2</sub> + HO<sub>2</sub> bimolecular rate constant was first shown by Andersson et al.,<sup>1</sup> who invoked formation of a HO<sub>2</sub>•CH<sub>3</sub>OH complex with ~25 kJ mol<sup>-1</sup> binding energy to explain their results. Since then, several other groups have quantified the effect on the HO<sub>2</sub> + HO<sub>2</sub> reaction (see Table 1). The only direct measurement of the equilibrium constant was carried out by Christensen et al.<sup>2</sup> from 231 to 261 K. Their measurements are the basis for this recommendation. They obtained Δ<sub>r</sub>H°(246 K) = -37.4 ± 4.8 kJ mol<sup>-1</sup> and Δ<sub>r</sub>S°(246 K) = -100 ± 19 J K<sup>-1</sup> mol<sup>-1</sup>. Christensen et al. also measured the forward and reverse rate constants and performed ab initio calculations, which are in reasonable agreement with the measured thermochemistry.

**6. HO<sub>2</sub> + CH<sub>2</sub>O → HOCH<sub>2</sub>OO.** The recommendation is based on the data of Barnes et al.,<sup>2</sup> Burrows et al.,<sup>4</sup> Veyret et al.,<sup>9</sup> and Morajkar et al.<sup>7</sup> All of these measurements, which are in good agreement with each other, relied on optical absorption to monitor the free radicals. The early measurement of Su et al.<sup>8</sup> is considerably higher, for unknown reasons, as are the measurements of Zabel et al.,<sup>10</sup> who utilized electron spin resonance to monitor the free radical concentrations. The temperature dependence reported by Zabel et al. is in good agreement with the current recommendation, although the reported absolute magnitude of Zabel et al.'s K<sub>eq</sub> is systematically about a factor of 6 or 7 greater. Theoretical work on this reaction has been reported by Evleth et al.,<sup>5</sup> Aloisio and Francisco,<sup>1</sup> Benson,<sup>3</sup> and Hermans et al.<sup>6</sup>

**7. HO<sub>2</sub> + CH<sub>3</sub>CHO → CH<sub>3</sub>CH(OH)OO.** Tomas et al.<sup>5</sup> measured this equilibrium constant from 298 to 373 K by using flash photolysis with time resolved UV absorption spectroscopy to monitor all three species (K<sub>eq</sub> ≈ 5.9 × 10<sup>-17</sup> cm<sup>3</sup> molecule<sup>-1</sup> at 298 K). Moortgat et al.<sup>3</sup> obtained product quantum yields from the photo-oxidation of CH<sub>3</sub>CHO in air. In carrying out their data analysis, which involved a complicated chemical mechanism, they estimated K<sub>eq</sub> ≈ 1 × 10<sup>-17</sup>

$\text{cm}^3 \text{molecule}^{-1}$  at 298 K. Morajkar et al.<sup>4</sup> used laser flash photolysis with cavity ring-down spectroscopy (CRDS) at 297 K to monitor  $\text{HO}_2$  radicals in real time; acetaldehyde concentrations were established by preparing gas mixtures (periodically checked in the cell by using laser induced fluorescence of OH and the known rate constant for  $\text{OH} + \text{CH}_3\text{CHO}$ ). In their experiments, the  $\text{HO}_2$  bi-exponential decays were used to extract  $K_{\text{eq}} = (1.7 \pm 0.5) \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1}$  at 298 K without the necessity of measuring the concentration of  $\text{CH}_3\text{CH(OH)OO}$  directly. The recommendation is based on the value obtained by Morajkar et al.<sup>4</sup> and the temperature dependence determined by Tomas et al.<sup>5</sup> error bounds were set large enough to include almost all of the reported data. Theoretical calculations have been reported by Aloisio and Francisco<sup>1</sup> and by Hermans et al.<sup>2</sup>

- 8.  $\text{HO}_2 + \text{CH}_3\text{C(O)CH}_3 \rightarrow \text{HO}_2\bullet\text{CH}_3\text{C(O)CH}_3$ .** The recommendation is based on the measured equilibrium constants that have been reported by Grieman et al.<sup>4</sup> and by Dillon et al.<sup>3</sup> The two sets of data are in excellent agreement with each other. Both groups measured the  $\text{HO}_2$  concentration with and without added acetone and identified the concentration difference with the concentration of the product (neither group observed the product adduct directly). Grieman et al. controlled the acetone concentration by temperature control of its vapor pressure and measured the  $\text{HO}_2$  concentration by tunable IR diode laser absorption. Dillon et al used UV absorption to monitor the  $\text{HO}_2$  and acetone concentrations. Both groups used information from theoretical calculations and other sources to determine that the product is the hydrogen bonded molecular complex (HBMC) and not the 2-hydroxyisopropylperoxy radical isomer that is expected to be formed subsequently by a "tail-biting" cyclic hydrogen transfer reaction (analogous to the one that occurs in the reaction of  $\text{HO}_2 + \text{CH}_2\text{O}$ ). Theoretical calculations at various levels of theory have been reported by Aloisio and Francisco,<sup>1</sup> Hermans et al.,<sup>6</sup> Hermans et al.,<sup>5</sup> Cours et al.,<sup>2</sup> and Dillon et al.<sup>3</sup>

- 11.  $\text{NO}_2 + \text{NO}_3$ .** The recommendation is based on the direct measurements of  $K_{\text{eq}}$  reported by Cantrell et al.,<sup>2</sup> Hjorth et al.,<sup>6</sup> and Osthoff et al.<sup>9</sup> As pointed out by Osthoff et al., the differences among the direct measurements of  $K_{\text{eq}}$  differ mostly because of calibration errors in the absorption coefficients of  $\text{NO}_2$ ,  $\text{N}_2\text{O}_5$ , and the  $\text{NO}_3$  free radical. The recommended pre-exponential factor (parameter "A") is the geometric mean of the values from Cantrell et al.,<sup>2</sup> Hjorth et al.,<sup>6</sup> and Osthoff et al.;<sup>9</sup> the recommended exponential parameter (i.e. parameter "B") is the average of the values reported in the same studies. The current recommendation is similar to the previous recommendation, which was based on the 'kinetics'  $K_{\text{eq}}$  reported by Cantrell et al.,<sup>3</sup> who carried out a thorough review of previous literature. They used their own measured rate constants for the decomposition reaction and the rate constants reported by Orlando et al.<sup>8</sup> for the recombination reaction to derive the 'kinetics'  $K_{\text{eq}}$ . The current recommendation is also in good agreement with the data of Burrows et al.<sup>1</sup> and with the room temperature data of Tuazon et al.<sup>14</sup> and of Perner et al.,<sup>10</sup> and with the exponential factor of Wängberg et al.,<sup>16</sup> although their absolute values of  $K_{\text{eq}}$  differ significantly, probably due to an unidentified calibration error. It is also in good agreement with the evaluation by Pritchard,<sup>11</sup> who reviewed the data of Cantrell et al.,<sup>2</sup> Burrows et al.,<sup>1</sup> Graham and Johnston,<sup>5</sup> Wängberg et al.,<sup>16</sup> Schott and Davidson,<sup>12</sup> and the room temperature data of Tuazon et al.,<sup>14</sup> Perner et al.,<sup>10</sup> and Hjorth et al.<sup>6</sup> Pritchard also included the values given by Smith et al.,<sup>13</sup> and Kircher et al.,<sup>7</sup> who combined data on the forward reaction with decomposition data of Connell and Johnston<sup>4</sup> and Viggiano et al.<sup>15</sup> (Table: 15-10 Note: 15-10, Evaluation: 15-10) [Back to Table](#)

- 13. CH<sub>3</sub>C(O)O<sub>2</sub> + NO<sub>2</sub>.** The recommendation is derived from measurements of the rate constants in both directions by Bridier et al.<sup>1</sup> These authors used the values of the rate constants at 298 K and a calculated value of the entropy change to get a third law value of the equilibrium constant. Their value of the enthalpy is exactly reproduced in a theoretical study by Miller et al.<sup>2</sup> A theoretical study by Wei et al.<sup>3</sup> is noted.

evaluation of thermochemical properties of selected radicals. Part I. *J. Phys. Chem. Ref. Data* **2005**, *34*, 573-656, doi:10.1063/1.1724828.

14. **CH<sub>3</sub>CH<sub>2</sub>C(O)O<sub>2</sub> + NO<sub>2</sub>.** Assumed to be the same as for PAN (Note 7). Both sides of the reaction differ from PAN by the group C-(C)(CO)(H)<sub>2</sub>. Error limits are estimated and expanded from those for PAN.  
(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)
15. **CH<sub>3</sub>C(O)CH<sub>2</sub> + O<sub>2</sub>.** Hassouna et al.<sup>1</sup> measured the rate constant and equilibrium constant for this reaction. The temperature range for the equilibrium measurements was 459 < T/K < 520. They extracted the entropy and enthalpy changes over this temperature range from a van't Hoff plot. (Second Law.) Values reported are  $\Delta S = -143.0 \pm 4.0 \text{ J mol}^{-1} \text{ K}^{-1}$  and  $\Delta H = -105.0 \pm 2.0 \text{ kJ mol}^{-1}$ . The value in Table 3 is computed assuming that these thermochemical values are constant to 200 K. They also performed quantum calculations, which confirmed the enthalpy measurement. They suggest  $\Delta H_{f,298}(\text{CH}_3\text{C(O)CH}_2) = -32.9 \pm 2.0 \text{ kJ mol}^{-1}$ .

17. **Cl + O<sub>2</sub>.** Data are from Baer et al.,<sup>1</sup> Nicovich et al.,<sup>3</sup> and Mauldin et al.<sup>2</sup> Zhu and Lin<sup>4</sup> have reported structure and frequency calculations and a heat of formation for ClOO. Using known thermochemistry for Cl and O<sub>2</sub> and entropy values for ClOO computed from Zhu and Lin,  $\Delta H_{f,0}(\text{ClOO}) = 23.85 \pm 0.1 \text{ kcal mole}^{-1}$  is obtained by the third law method from the individual data points of the Nicovich et al.<sup>3</sup> data. The Baer et al.<sup>1</sup> paper reports only one value at each temperature and only graphically, but yields essentially the same value as Nicovich et al.<sup>3</sup> The third law value from Mauldin et al.<sup>2</sup> is less stable by 0.4 kcal mole<sup>-1</sup>. Earlier values, both experimental and theoretical, of the structural parameters of ClOO are referenced in Zhu and Lin.<sup>4</sup>  $S^{\circ}_{298}(\text{ClOO}) = 64.6 \text{ cal mole}^{-1} \text{ K}^{-1}$  and  $\Delta H_{f,298}(\text{ClOO}) = 23.5 \pm 0.5 \text{ kcal mole}^{-1}$  are recommended.

- 19. ClO + O<sub>2</sub>.** DeMore<sup>2</sup> reports  $K_{eq} < 4 \times 10^{-18}$  cm<sup>3</sup> molecule<sup>-1</sup> at 197 K. His temperature dependence of the equilibrium constant is estimated using  $S^\circ_{298}$  (ClO•O<sub>2</sub>) = 73 cal mol<sup>-1</sup> K<sup>-1</sup> and  $\Delta H^\circ_{298} < 7.7$  kcal mol<sup>-1</sup>. A higher value of  $K_{eq}$  has been proposed by Prasad,<sup>3</sup> but it requires  $S^\circ$ (ClO•O<sub>2</sub>) to be about 83 cal mol<sup>-1</sup> K<sup>-1</sup>, which seems unreasonably high. Carter and Andrews<sup>1</sup> found no experimental evidence for ClO•O<sub>2</sub> in matrix experiments. Prasad and Lee<sup>4</sup> discuss these issues and question the validity of the upper limit reported by DeMore.

- 20. (a) ClO + ClO  $\rightarrow$  ClOOCl.** The values of the equilibrium constant and the thermochemical parameters are from a third-law calculation based on the data of Hume et al.,<sup>12</sup> which span temperatures from 206 K to 250 K. A second-law analysis of the data of Hume et al. is highly consistent with the third-law results. The data of Hume et al. are statistically much more precise than previous studies and extend to lower temperatures, which are more relevant to the stratosphere. The recommendation is generally consistent with the data of Cox and Hayman<sup>7</sup> and Nicklaisen et al.,<sup>16</sup> which were the basis for the previous recommendation. The 95% error limits were chosen to incorporate all the data points in these two studies and to include the error range estimated by Hume et al. The entropy of ClOOCl (302.9 J mol<sup>-1</sup> K<sup>-1</sup> at 298 K) was calculated from rotational constants measured by Birk et al.,<sup>3</sup> four vibrational frequencies measured by Jacobs et al.,<sup>13</sup> and two frequencies computed by Matus et al.<sup>15</sup> The entropy values are in close agreement with those calculated by Zhu and Lin<sup>22</sup> (symmetry number corrected by Golden<sup>10</sup> to account for optical isomers) or by treatment of the torsion as a hindered rotor<sup>2</sup>, in which case the symmetry number correction is not required. From the third-law analysis, the ClOOCl heat of formation at 0 K and 298 K are  $\Delta H_{f,0} = 133.3 \pm 1$  kJ mol<sup>-1</sup> and  $\Delta H^\circ_{f,298} = 130.1 \pm 1$  kJ mol<sup>-1</sup>, in good agreement with the analysis of Hume et al. A study of branching ratios of ClO + ClO channels in Cl<sub>2</sub>/O<sub>2</sub>/O<sub>3</sub> mixtures by Horowitz et al.<sup>11</sup> also finds the equilibrium constant in O<sub>2</sub> at 285 K to be in agreement with the recommendation. Values at single temperatures from Ellermann et al.<sup>8</sup> and from Boakes et al.<sup>4</sup> fall within the 95% confidence limit. Broske and Zabel<sup>5</sup> measured the reverse reaction at four temperatures between 245 and 260 K. They used the parameters for the forward reaction recommended in JPL 02-25 to suggest van't Hoff parameters of  $5.09 \times 10^{-26}$  and 7584. van't Hoff parameters suggested by Plenge et al.,<sup>17</sup> who measured  $\Delta H_{f,0}(\text{ClOOCl}) = 134.0 \pm 2.80$  kJ mol<sup>-1</sup> by photoionization mass spectrometry and computed the entropy change for the reaction, are  $1.92 \times 10^{-27}$  and 8430. Ferracci and Rowley<sup>9</sup> report values of  $K_{eq}$  between 250 and 313 K that also fall within the 95% confidence limits. Several studies have derived values of  $K_{eq}$  using atmospheric measurements in the nighttime polar stratosphere under conditions where ClO and ClOOCl should be in equilibrium. These are summarized here but are not used in the derivation of the recommended equilibrium constants. Avallone and Toohey<sup>1</sup> used  $K_{eq} = 1.99 \times 10^{-30} \times T \times \exp(8854/T)$  derived from *in situ* aircraft experiments. The Avallone and Toohey<sup>1</sup> expression yields values that are quite close to those from the recommended expression. Atmospheric measurements from an airborne platform have also been used by von Hobe et al.<sup>21</sup> to deduce  $K_{eq}$  parameters of  $3.61 \times 10^{-27}$  and 8167, resulting in values which lie close to the lower 95% confidence limit. A reanalysis by Salawitch and Carty<sup>18</sup> of ER-2 data between 185 and 200 K, from Stimpfle et al.<sup>20</sup> results in an expression for  $K_{eq}$  which lies within the uncertainty bounds and is quite close to the Avallone and Toohey<sup>1</sup> expression. Santee et al.<sup>19</sup> report measurements in the Arctic and Antarctic night by satellite based instruments, which are close to the current recommendation. The recent analysis by Kleinböhl et al.<sup>14</sup> is also consistent with the current recommendation.
- (Table 15-10, Note: 15-10, Evaluated: 15-10)
- (b) ClO+ClO  $\rightarrow$  ClOCIO.** Zhu and Lin<sup>22</sup> used the G2 composite method to calculate the bond dissociation energy  $D_0(\text{ClO-ClO}) = 49.8$  kJ mol<sup>-1</sup>. Matus et al.<sup>15</sup> used the CCSD(T)/aug-cc-pV(5+d)Z method extrapolated to the complete basis set limit and found that ClOCIO is less strongly bound than ClOOCl by 33.9 kJ mol<sup>-1</sup> at 298 K (Matus et al. estimate their errors to be less than 4.2 kJ mol<sup>-1</sup>). Combining this value from Matus et al. with  $\Delta H_{f,298}(\text{ClOCIO}) = 130.1 \pm 1$  kJ mol<sup>-1</sup> gives  $\Delta H_{f,298}(\text{ClOCIO}) = 164.0 \pm 5$  kJ/mol ( $\Delta H_{f,0} = 166.5 \pm 5$  kJ/mol) for ClOCIO. The vibrational

frequencies and moments of inertia calculated by Matus et al. are in good agreement with those of Zhu and Lin<sup>22</sup> and Chase<sup>6</sup>. The entropy of ClOClO was calculated using the harmonic frequencies from Matus et al.,<sup>15</sup> anharmonicities computed by Maranzana (2007, unpublished), and rotational constants from Chase,<sup>6</sup> giving  $S^{\circ}_{298}(\text{ClOClO}) = 312.6 \text{ J K}^{-1} \text{ mol}^{-1}$ . Thermodynamic data for ClO radicals were taken from Chase.<sup>6</sup> The 1-sigma errors in  $\Delta S_{r,298}$  and  $\Delta H_{r,298}$  are estimated to be  $6 \text{ J K}^{-1} \text{ mol}^{-1}$  and  $6 \text{ kJ mol}^{-1}$ , respectively. Using these parameters, the equilibrium constant is given by  $K_{\text{eq}}(\text{ClOClO}) = 6.5 \times 10^{-27} \times \exp(4460/T)$  with uncertainty factors  $f(298) = 2$  and  $g = 600$ .

- 21. Cl + OCIO.** Because of the high energy barriers calculated for other plausible pathways (ClO + ClO or isomerization of ClOOCl and ClOCIO), this pathway seems to be the most relevant for formation and dissociation of ClClO<sub>2</sub>

(chloryl chloride). Zhu and Lin<sup>6</sup> found energy barriers of >19 kcal mol<sup>-1</sup> separating ClClO<sub>2</sub> from ClOOCl and ClOClO; they did not identify any low energy paths from ClO + ClO. It is noteworthy that Bröske and Zabel<sup>1</sup> did not see any evidence for formation of ClClO<sub>2</sub> when they measured the gas phase thermolysis of ClOOCl, although they were able to measure ClClO<sub>2</sub> produced in wall reactions. Thus it seems unlikely that the gas phase isomerization reactions are fast enough to be significant. The recommended K<sub>eq</sub> is based on the thermodynamic calculation. The vibrational frequencies and moments of inertia are known,<sup>4,5</sup> giving S°<sub>298</sub> (ClClO<sub>2</sub>) = 294.4 J K<sup>-1</sup> mol<sup>-1</sup>. The heat of formation of ClClO<sub>2</sub> has not been measured, but it has been calculated many times (see Zhu and Lin<sup>6</sup> for a summary of calculations up to 2003). The CCSD(T) calculations by Lee et al.<sup>2</sup> with large ANO basis sets was formerly regarded as the best. Recently, Matus et al.<sup>3</sup> carried out even better calculations (i.e., CBS(Q5)) and concluded that ΔH<sub>f,0</sub>(ClClO<sub>2</sub>) is 3.5 kcal mol<sup>-1</sup> below that of ClOOCl. Matus et al. estimate their relative errors to be less than ±1 kcal mol<sup>-1</sup>. Coupled with the recommended value of 132.4 ± 3 kJ/mol for ClOOCl (see Note 14a), this gives ΔH<sub>f,0</sub>(ClClO<sub>2</sub>) = 117.8 kJ/mol and ΔH<sub>r,298</sub> = 113.7 kJ/mol. The 1-sigma errors in ΔS<sub>r,298</sub> and ΔH<sub>r,298</sub> are estimated to be 6 J K<sup>-1</sup> mol<sup>-1</sup> and 5 kJ mol<sup>-1</sup>, respectively.

- 22. ClO + OCIO.** Data are from Burkholder et al.,<sup>2</sup> Hayman and Cox,<sup>5</sup> and Green et al.<sup>4</sup> The best van't Hoff fit to all the data yields the recommended parameters. The 95% error limits encompass all the data. A calculation of the entropy and heat capacity from the structure and frequencies of ClOCl(O)O reported by Zhu and Lin<sup>8</sup> allows a "3rd Law" fit that gives K<sub>eq</sub>/cm<sup>-1</sup> molecule<sup>-1</sup> = 1.6 × 10<sup>-27</sup> exp(7155/T) for 232 < T/K < 298. By including the hindered rotor potential explicitly,<sup>1</sup> a new "3rd Law" fit obtained by fitting the data of Burkholder et al.<sup>2</sup> and Hayman and Cox,<sup>5</sup> including the lowest temperature point, gives the new recommendation: S°<sub>298</sub> (Cl<sub>2</sub>O<sub>3</sub>) = 337.8 J K<sup>-1</sup> mol<sup>-1</sup> (80.7 cal mol<sup>-1</sup> K<sup>-1</sup>) and ΔH<sub>f,0</sub> (Cl<sub>2</sub>O<sub>3</sub>) = 143.9 kJ mol<sup>-1</sup> (34.4 kcal mol<sup>-1</sup>) and ΔH<sub>r,298</sub> (Cl<sub>2</sub>O<sub>3</sub>) = 138.9 kJ mol<sup>-1</sup> (33.2 kcal mol<sup>-1</sup>). This compares to calculated values of ΔH<sub>f,0</sub>(Cl<sub>2</sub>O<sub>3</sub>) = 32.3 kcal mol<sup>-1</sup> from Zhu and Lin<sup>8</sup> and 32.9 kcal mol<sup>-1</sup> from Sicre and Cobos.<sup>7</sup> Burkholder et al.<sup>2</sup> reported that treating the lowest vibration as a free internal rotation increases the entropy of ClOCl(O)O by almost 9 cal mol<sup>-1</sup> K<sup>-1</sup>, but this value, repeated by Green et al.,<sup>4</sup> is not correct. Clark and Francisco,<sup>3</sup> who calculated structure and frequencies, concluded that S°<sub>298</sub> (Cl<sub>2</sub>O<sub>3</sub>) = 78.5 cal mol<sup>-1</sup> K<sup>-1</sup>, based on harmonic frequencies. Li et al.<sup>6</sup> have also reported theoretical structure and frequencies in general agreement with Zhu and Lin<sup>8</sup> and Clark and Francisco,<sup>3</sup> but energetics that are quite different.

- 23. OCIO + NO<sub>3</sub>.** From theoretical calculations of Parthiban et al.<sup>2</sup> This value replaces the value that was previously deduced by Friedl et al.<sup>1</sup> Uncertainties are based on an assumed  $\pm 1$  kcal mole<sup>-1</sup> uncertainty in the calculated heat of formation.  
 (Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Friedl, R. R.; Sander, S. P.; Yung, Y. L. Chloryl nitrate: A novel product of the OCIO + NO<sub>3</sub> + M recombination. *J. Phys. Chem.* **1992**, *96*, 7490-7493.
  - (2) Parthiban, S., T. J. Lee, S. Guha, and J. S. Francisco Theoretical study of chlorine nitrates: Implications for stratospheric chlorine chemistry. *J. Am. Chem. Soc.* **2003**, *125*, 10446-10458, doi:10.1021/ja010297g.
- 24. Br + CH<sub>2</sub>=C(CH<sub>3</sub>)CH=CH<sub>2</sub> (isoprene).** In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF<sub>2</sub>Br<sub>2</sub> precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.<sup>1</sup> determined K<sub>eq</sub> from 210 to 298 K. The adduct(s) produced in the reaction are not known, but may consist of several isomers; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is BrH<sub>2</sub>CC(CH<sub>3</sub>)CH=CH<sub>2</sub>. Analysis of the data by 2<sup>nd</sup> Law and by 3<sup>rd</sup> Law methods produced results in good mutual agreement. Laine et al. averaged the 2<sup>nd</sup> Law and 3<sup>rd</sup> Law results to obtain  $\Delta_r H^{298} = -67.5 \pm 6.6$  kJ mol<sup>-1</sup>, and  $\Delta_r S^{298} = -93 \pm 16$  J K<sup>-1</sup> mol<sup>-1</sup>. The present recommendation is based on a 3<sup>rd</sup> Law analysis. The recommended error parameters are larger than the 40% 2 $\sigma$  relative errors (including both statistical and systematic) estimated by Laine et al.; they are set so that all of the K<sub>eq</sub> data fall within the 2 $\sigma$  error limits and an extra margin was added because only one determination of K<sub>eq</sub> has been reported for this reaction.  
 (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)
- (1) Laine, P. L.; Sohn, Y. S.; Nicovich, J. M.; McKee, M. L.; Wine, P. H. Kinetics of elementary steps in the reactions of atomic bromine with isoprene and 1,3-butadiene under atmospheric conditions. *J. Phys. Chem. A* **2012**, *116*, 6341-6357, doi:10.1021/jp212127v.
- 25. Br + CH<sub>2</sub>=CHCH=CH<sub>2</sub> (1,3-butadiene).** In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF<sub>2</sub>Br<sub>2</sub> precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.<sup>1</sup> determined K<sub>eq</sub> from 227 to 298 K; they estimated the 2 $\sigma$  relative error to be ~40%. The adduct(s) produced in the reaction were not measured directly, but calculations (G4 method) by Laine et al. predict that the adduct formed by addition of Br to the terminal carbon is favored thermodynamically. Analysis of the data by 2<sup>nd</sup> Law and by 3<sup>rd</sup> Law methods produced results in fair mutual agreement. Laine et al. averaged the 2<sup>nd</sup> Law and 3<sup>rd</sup> Law results to obtain  $\Delta_r H^{298} = -64.5 \pm 8.5$  kJ mol<sup>-1</sup> and  $\Delta_r S^{298} = -94 \pm 20$  J K<sup>-1</sup> mol<sup>-1</sup>, which provide the basis for the current recommendation. The recommended error parameters are larger than the 40% 2 $\sigma$  relative errors (including both statistical and systematic) estimated by Laine et al.; they are set so that all of the K<sub>eq</sub> data of Laine et al. fall within the 2 $\sigma$  error limits and an extra margin was added because only one determination of K<sub>eq</sub> has been reported for this reaction.

- 28.  $\text{Cl} + \text{CS}_2$ .** Fit to the data of Nicovich et al.<sup>1</sup> between 193 and 258 K.  
(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)
- (1) Nicovich, J. M.; Wine, P. H. Kinetics of the reactions of  $\text{O}({}^3P)$  and  $\text{Cl}({}^2P)$  with  $\text{HBr}$  and  $\text{Br}_2$ . *Int. J. Chem. Kinet.* **1990**, *22*, 379-397.
- 29.  $\text{CH}_3\text{S} + \text{O}_2$ .** Turnipseed et al.<sup>6</sup> generated  $\text{CH}_3\text{S}$  radicals by pulsed laser photolysis of  $\text{CH}_3\text{SCH}_3$  in an excess of  $\text{O}_2$  and used LIF of  $\text{CH}_3\text{S}$  to monitor the subsequent reaction. Biexponential decays were observed, signaling the reversible formation of a weakly bound complex. The equilibrium constant was extracted in the data analysis over a range of temperatures from 216 to 258 K and a van't Hoff (2<sup>nd</sup> Law) analysis gives  $K_{\text{eq}} = 7.9 \times 10^{-27} \exp(4978/T) \text{ cm}^3 \text{ molecule}^{-1}$ . In a different experimental system, Butkovskaya and Barnes<sup>1</sup> (cited by Chu and Lee<sup>2</sup>) measured  $K_{\text{eq}} = 1.4 \times 10^{-19}$  at 298 K, in good agreement with the 2<sup>nd</sup> Law expression given above for  $K_{\text{eq}}$ . The molecular properties of  $\text{CH}_3\text{SOO}$  have been computed in several theoretical studies<sup>4,5,7,8</sup> and some vibrational transitions have been observed by FTIR.<sup>2</sup> The recommendation is based on a new 3rd Law analysis of the data of Turnipseed et al.<sup>6</sup> This analysis made use of vibrational frequencies and rotational constants obtained from Chu and Lee<sup>2</sup> and from the NIST CCCBDB database.<sup>3</sup> The value of  $K_{\text{eq}}(298 \text{ K})$  obtained by Butkovskaya and Barnes is in excellent agreement with the recommendation. The bond dissociation energies at 0 K and 298 K obtained in this 3<sup>rd</sup> Law analysis are 39.5 and 42.2  $\text{kJ mol}^{-1}$ , respectively; the computed entropy of  $\text{CH}_3\text{SOO}$  at 298 K is 316.7  $\text{J K}^{-1} \text{ mol}^{-1}$ .

- 30.  $\text{OH} + (\text{CH}_3)_2\text{S} \rightarrow (\text{CH}_3)_2\text{SOH}$ .** This recommendation is based on the results of Hynes et al.<sup>3</sup> and Barone et al.,<sup>1</sup> who used deuterated dimethyl sulfide (DMS-d<sub>6</sub>), and Williams et al.,<sup>7</sup> who used both DMS-d<sub>6</sub> and non-deuterated DMS-d<sub>0</sub>, in studies of the rate constants for the reaction and found clear evidence for adduct formation. In each case,  $K_{\text{eq}}$  was obtained by analyzing the rate constant data, which showed double-exponential decays. Hynes et al.<sup>3</sup> measured  $K_{\text{eq}}$  from 250–267 K and reported an adduct bond energy of  $13.0 \pm 3.3 \text{ kcal/mol}$  from a van't Hoff (2<sup>nd</sup> Law) analysis and a bond energy of  $10.1 \pm 1.1 \text{ kcal/mol}$  based on a 3<sup>rd</sup> Law analysis using the theoretical molecular parameters computed by McKee.<sup>4</sup> Barone et al. measured  $K_{\text{eq}}$  from 217–240 K and reported bond energies of 10.2 and  $10.7 \pm 2.5 \text{ kcal/mol}$  from 2<sup>nd</sup> and 3<sup>rd</sup> Law calculations, respectively. Williams et al. analyzed only their  $K_{\text{eq}}$  data for  $\text{OH} + \text{DMS-d}_6$  (240–245 K) and obtained bond strengths of  $10.9 \pm 1.0 \text{ kcal/mol}$  from a 2<sup>nd</sup> Law analysis and 10.5  $\text{kcal/mol}$  from a 3<sup>rd</sup> Law analysis based on their own MP2/6-31+G(2d,p) quantum chemical calculations (in good agreement with McKee).<sup>5</sup> The present recommendation was obtained from a 3<sup>rd</sup> Law analysis of the data for  $\text{OH} + \text{DMS-d}_6$  from all three DMD-d<sub>6</sub> studies combined with the data for  $\text{OH} + \text{DMS-d}_0$  from Williams et al. The 61 data points covered the temperature range from 217–261 K. The 3<sup>rd</sup> Law analysis used the theoretical molecular parameters for DMS and HODMS computed by Williams et al.<sup>7</sup> and the properties of the OH radical from the JANAF<sup>2</sup> Tables and Ruscic et al.<sup>6</sup>

to obtain the dissociation energy (without zero point energies)  $D_e = 55.5 \pm 1.3$  kJ/mol ( $2\sigma$ ). When the zero point energy differences are taken into account, this gives dissociation energies  $D_0(\text{HO-DMS-d}_6) = 43.2 \pm 1.3$  kJ/mol and  $D_0(\text{HO-DMS-d}_0) = 43.0 \pm 1.3$  kJ/mol ( $2\sigma$ ).

**32. IO + NO<sub>2</sub>.** The parameters were computed based on a combination of experimental and theoretical data. The rovibrational parameters and electronic energy levels for IO radical and NO<sub>2</sub> were obtained from the NIST/JANAF tables;<sup>2</sup> rovibrational parameters for IONO<sub>2</sub> were obtained from Marshall.<sup>5</sup> The IO-NO<sub>2</sub> bond dissociation energy ( $D_0$ ) is relatively uncertain, but estimates are provided by several recent publications. Golden<sup>3</sup> carried out RRKM/master equation calculations and concluded that  $D_0$  is ~150 kJ/mol. Kaltsoyannis and Plane<sup>4</sup> obtained 117.9 kJ/mol from quantum chemical calculations at the CCSD(T)/aug-cc-pVTZ // B3LYP/aug-cc-pVTZ level of theory. Saiz-Lopes et al.<sup>9</sup> reported a rounded value of 118 kJ/mol in their recent review article. Marshall<sup>5</sup> obtained 113.6 ( $\pm 3.1$ ) kJ/mol from quantum chemical calculations at the CCSD(T)/aug-cc-pVTZ // CCSD(T)/aug-cc-pVTZ level of theory. The  $K_{eq} = A \times \exp(B/T)$  parameters computed based on  $D_0$  from Golden, from Kaltsoyannis and Plane, and from Marshall are  $A = 5.02 \times 10^{-28}$  ( $\pm 10\%$ ) and  $B = 18240$ , 14380, and 13860. The recommendation is based on the average of the latter two. The entropy of IONO<sub>2</sub> computed using this model is  $S(298) = 320.95 \text{ J K}^{-1} \text{ mol}^{-1}$ . In earlier work, Rayez and Destriau<sup>8</sup> reported  $D_0 = 134 \pm 13$  kJ/mol, Allan and Plane<sup>1</sup> reported  $D_0 = 94.9$  kJ/mol and Papayannis and Kosmas<sup>6,7</sup> reported  $D_0$  values from 131.4 to 137.6 kJ/mol.

- 33. Hg + Br.** This equilibrium constant has never been measured directly. Goodsite et al.<sup>2</sup> used statistical rate theory combined with atomic and molecular properties to calculate the forward and reverse rate constants, from which K<sub>eq</sub> can be obtained. Later, Goodsite et al.<sup>3</sup> recomputed the rate constants with an updated HgBr bond dissociation energy (assumed to be 66.3 kJ mol<sup>-1</sup>, which is the average of the spectroscopic determination by Tellinghuisen and Ashmore,<sup>5</sup> the computed value (CCSD(T)) from Shepler et al.,<sup>4</sup> and the JANAF value (from 1961) and obtained K<sub>eq</sub> = 9.1 × 10<sup>-24</sup> exp(7984/T). The spectroscopic determination of Tellinghuisen and Ashmore gives D<sub>e</sub> = 5525 ± 100 cm<sup>-1</sup> (66.1 ± 1.2 kJ mol<sup>-1</sup>), where the uncertainty arises from the extrapolation of the assigned vibrational levels to the dissociation limit. Dibble et al.<sup>1</sup> used this spectroscopic value in a direct statistical mechanics calculation, obtaining K<sub>eq</sub> = 9.1 × 10<sup>-24</sup> exp(7801 ± 201/T). The recommendation is based on the calculation of Dibble et al.,<sup>1</sup> with error limits assigned to accommodate the calculation of Goodsite et al.<sup>3</sup>

## SECTION 4. PHOTOCHEMICAL DATA

### Table of Contents

SECTION 4. PHOTOCHEMICAL DATA .....	4-1
4.1 Format and Uncertainty Estimates.....	4-6
4.2 Photodissociation Thresholds and Quantum Yields .....	4-6
4.3 Web Access to Recommended Data in Text and Graphical Formats.....	4-7
SECTION 4A. O <sub>x</sub> PHOTOCHEMISTRY .....	4-11
4.4 Bibliography – O <sub>x</sub> Photochemistry .....	4-32
SECTION 4B. HO <sub>x</sub> PHOTOCHEMISTRY .....	4-39
4.5 Bibliography – HO <sub>x</sub> Photochemistry .....	4-49
SECTION 4C. NO <sub>x</sub> PHOTOCHEMISTRY .....	4-53
4.6 Bibliography – NO <sub>x</sub> Photochemistry .....	4-83
SECTION 4D. ORGANIC PHOTOCHEMISTRY .....	4-90
4.7 Bibliography – Organic Photochemistry .....	4-148
SECTION 4E. FO <sub>x</sub> PHOTOCHEMISTRY .....	4-157
4.8 Bibliography – FO <sub>x</sub> Photochemistry.....	4-186
SECTION 4F. CLO <sub>x</sub> PHOTOCHEMISTRY .....	4-189
4.9 Bibliography – ClO <sub>x</sub> Photochemistry .....	4-270
SECTION 4G. BRO <sub>x</sub> PHOTOCHEMISTRY .....	4-280
4.10 Bibliography – BrO <sub>x</sub> Photochemistry .....	4-335
SECTION 4H. IO <sub>x</sub> PHOTOCHEMISTRY .....	4-340
4.11 Bibliography – IO <sub>x</sub> Photochemistry .....	4-384
SECTION 4I. SO <sub>x</sub> PHOTOCHEMISTRY .....	4-389
4.12 Bibliography – SO <sub>x</sub> Photochemistry .....	4-397
SECTION 4J. METAL PHOTOCHEMISTRY .....	4-399
4.13 Bibliography – Metal Photochemistry .....	4-404

### Figures

Figure 4A-1. Recommended O( <sup>1</sup> D) Quantum Yields.....	4-27
Figure 4C-1. Absorption Spectrum of NO <sub>3</sub> .....	4-64
Figure 4F-1. Absorption Spectrum of ClO .....	4-192
Figure 4F-2. Absorption Spectrum of OCIO at 204 K.....	4-199
Figure 4G-1. Absorption Spectrum of BrO .....	4-287
Figure 4G-2. Absorption spectrum of OBrO .....	4-290

### Tables

## 4.1 Format and Uncertainty Estimates

Table 4-1 is a list of the photochemical reactions included in this evaluation and considered to be of atmospheric interest. The ultraviolet (UV) absorption spectra of O<sub>2</sub> and O<sub>3</sub> largely determine the extent of the penetration of solar radiation into the stratosphere and troposphere. Some comments and references to these spectra and their cross sections,  $\sigma(\lambda, T)$ , are presented, but only a sample of the data is provided here (for further detail see WMO Report No. 11;<sup>1</sup> WMO Report No. 16<sup>5</sup>). The photodissociation of NO in the O<sub>2</sub> Schumann-Runge band spectral range is another important process requiring special treatment and is not discussed in this evaluation (see Frederick and Hudson,<sup>3</sup> Allen and Frederick,<sup>2</sup> WMO Report No. 11,<sup>1</sup> and Minschwaner and Siskind<sup>4</sup>).

Some species included in this evaluation have highly structured spectra, e.g. SO<sub>2</sub>. Notes are provided for these molecules, but complete photochemical data are not presented in all cases. The species CH<sub>2</sub>O, NO<sub>2</sub>, NO<sub>3</sub>, ClO, BrO, and OCIO have complicated spectra, but in view of their importance for atmospheric chemistry a sample of the data is presented in the evaluation. Detailed information on their high-resolution spectra and the temperature dependence of the spectrum should to be obtained from the original cited literature.

The absorption cross sections are defined by the following expression of Beer's Law:

$$I = I_0 \exp(-\sigma(\lambda, T) n L)$$

where I<sub>0</sub> and I are the incident and transmitted light intensity, respectively,  $\sigma$  is the absorption cross section in cm<sup>2</sup> molecule<sup>-1</sup> at wavelength  $\lambda$  and temperature T, n is the concentration in molecule cm<sup>-3</sup>, and L is the pathlength in cm.

Estimates of the uncertainty in  $\sigma(\lambda, T)$  are provided within the Notes for many of the molecules included in this evaluation, but not all. The reported uncertainty factors are not rigorous numbers resulting from a detailed statistical error propagation analysis of the available data sets. Rather, they represent a consensus among the panel members as to the reliability of the data, taking into account the difficulty of the measurements and the agreement among the results reported by various groups. The uncertainty in  $\sigma(\lambda, T)$  is, in most cases, expected to be wavelength and temperature dependent, e.g. the uncertainty in wavelength regions with weak absorption or at low temperatures representative of the upper troposphere-lower stratosphere are usually more uncertain. The recommended uncertainty factors are primarily based on the wavelength regions most critical to atmospheric photolysis processes.

## 4.2 Photodissociation Thresholds and Quantum Yields

The threshold energies for the photolysis channels given in the notes, and the corresponding wavelengths, were calculated using the 298 K heats of formation,  $\Delta H_f(298\text{ K})$  given in the Thermochemical Parameters section of this evaluation.

The primary process in the photodissociation of chlorinated hydrocarbons is well established: absorption of ultraviolet radiation in the lowest frequency band is interpreted as an n-σ\* transition involving excitation to a repulsive electronic state (anti-bonding in C-Cl), which dissociates by breaking the carbon-chlorine bond (Majer and Simons<sup>2</sup>). As expected, chlorofluoromethanes, which are a particular type of chlorinated hydrocarbons, behave in this fashion (Sandorfy<sup>3</sup>). The quantum yield for photodissociation is expected to be unity for these compounds. There are several studies that show specifically that this is the case for CF<sub>2</sub>Cl<sub>2</sub>, CFCl<sub>3</sub>, and CCl<sub>4</sub>. These studies also indicate that at shorter wavelengths that two halogen atoms can be released simultaneously in the primary process.

The mechanism for the photodissociation of other classes of compounds, such as aldehydes and ketones, in many cases includes multiple product channels, where the different channels may have different impacts on atmospheric chemistry. Photolysis quantum yields may also display a wavelength, pressure, and temperature dependence. Detailed quantum yield studies are presently not available for all molecules included in this evaluation. Quantum yield recommendations are made were possible.

(Recommendation: 10-6, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The photodissociation of molecular oxygen in the stratosphere is due primarily to the absorption of solar radiation in the 200–240 nm wavelength region, i.e., within the Herzberg continuum, which arises from the A<sup>3</sup>Σ<sub>u</sub><sup>+</sup> ← X<sup>3</sup>Σ<sub>g</sub><sup>-</sup> transition. Between 240 and 300 nm the absorption spectrum is also due to the electronic transition from the ground X<sup>3</sup>Σ<sub>g</sub><sup>-</sup> state to excited electronic states A<sup>3</sup>Σ<sub>u</sub><sup>+</sup> ← X<sup>3</sup>Σ<sub>g</sub><sup>-</sup> (Herzberg I), c<sup>1</sup>Σ<sub>u</sub><sup>-</sup> ← X<sup>3</sup>Σ<sub>g</sub><sup>-</sup> (Herzberg II), and A' <sup>3</sup>Δ<sub>u</sub> ← X<sup>3</sup>Σ<sub>g</sub><sup>-</sup> (Herzberg III). The 175–205 nm region, the O<sub>2</sub> Schumann-Runge (B<sup>3</sup>Σ<sub>g</sub><sup>-</sup> ← X<sup>3</sup>Σ<sub>g</sub><sup>-</sup>) band spectral range, is also very important, since solar radiation penetrates efficiently into the stratosphere at these wavelengths. The Schumann-Runge band system is composed of rotational lines with widths on the order of 1 cm<sup>-1</sup>. The peak absorption cross sections in the Schumann-Runge system span ~5 orders of magnitude.

**Table 4A-1. Summary of O<sub>2</sub> Absorption Cross Section Studies**

Study	Year	Molecule <sup>a</sup>	Wavelength (nm)	Resolution (nm)	Temperature (K)

Measurements of the absorption cross sections in the VUV have mainly been reported at low resolution during the period from 1952 to 1979 as listed in Table 4A-1. High resolution cross sections have been reported by Cole and Dexter,<sup>23</sup> Brion et al.,<sup>14</sup> Gibson et al.,<sup>30</sup> Ahmed et al.,<sup>5</sup> Wu et al.,<sup>87</sup> and Yoshino et al.<sup>101</sup>

At the Lyman-α wavelength (121.567 nm), absorption cross section values at 298 K were reported (in cm<sup>2</sup> molecule<sup>-1</sup>) by Preston<sup>70</sup> ( $1.17 \times 10^{-20}$ ), Watanabe et al.<sup>82</sup> ( $1.23 \times 10^{-20}$ ), Ogawa<sup>64</sup> ( $1.03 \times 10^{-20}$ ), Kley<sup>44</sup> ( $1.13 \times 10^{-20}$ ), and Lewis et al.<sup>53</sup> ( $9.1 \times 10^{-21}$ ). The latter authors measured the temperature dependence of the cross sections in the range 84–366 K. A value of  $(1.1 \pm 0.1) \times 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup> is recommended at 298 K. Kley<sup>44</sup> measured the pressure dependence of the Lyman-α cross section in the pressure range 20–880 Torr and in the temperature range 208–305 K. The cross sections were parameterized by the following equation:  $\sigma_{O_2} = (1.13 \pm 0.09) \times 10^{-20} + (1.72 \pm 0.21) \times 10^{-23} \times P$  where P is the pressure in Torr.

In the Herzberg continuum (200–240 nm) Frederick and Mentall,<sup>29</sup> Herman and Mentall,<sup>34</sup> Anderson and Hall,<sup>7,8</sup> and Pirre et al.<sup>68,69</sup> estimated O<sub>2</sub> absorption cross sections from balloon measurements of solar irradiance in the stratosphere. These authors found the cross sections in the 200–210 nm range to be ~35% smaller than the smallest of the older laboratory results, which are those of Ditchburn and Young,<sup>27</sup> Hasson and Nichols,<sup>33</sup> Ogawa,<sup>65</sup> Sharananand,<sup>74</sup> and Sharananand and Prasad Rao.<sup>75</sup> The more recent laboratory studies (Johnston et al.,<sup>42</sup> Cheung et al.,<sup>18,20</sup> and Jenouvrier et al.<sup>40,41</sup>) confirm the lower values obtained from solar irradiance measurements. The recommended absorption cross section values between 205 and 240 nm are based on the data of Cheung et al.<sup>20</sup> and Jenouvrier et al.<sup>40</sup> and were evaluated by Yoshino et al.<sup>88</sup> as listed in Table 4A-2. The recommended values from 241–245 nm are from Fally et al.<sup>28</sup> (see below). Amoruso et al.<sup>6</sup> have also carried out cross section measurements in the wavelength range 208–240 nm of the Herzberg continuum; their values are ~15% lower than those reported by Yoshino et al.<sup>88</sup> Coquart et al.<sup>26</sup> have reported Herzberg continuum absorption cross sections at 219 K in the wavelength region 196–205 nm of the S-R bands, in agreement with the determinations of Cheung et al.<sup>18,20</sup> and Ogawa<sup>65</sup> and in line with the data of Yoshino et al.<sup>88</sup> Calculations of the absorption continua in the range 195–300 nm were performed by Saxon and Slanger.<sup>73</sup> Cross sections at elevated temperatures (up to 1073 K) and pressures (up to 6 bar) were reported by Vattulainen et al.<sup>79</sup>

**Table 4A-2. Recommended Absorption Cross Sections of O<sub>2</sub> between 205 and 245 nm**

$\lambda$ (nm)	$10^{24} \sigma$ (cm <sup>2</sup> )	$\lambda$ (nm)	$10^{24} \sigma$ (cm <sup>2</sup> )

224	3.67	245	0.05
225	3.45		

Note:

205–240 nm: Yoshino et al.<sup>88</sup>241–245 nm: Fally et al.<sup>28</sup>

The penetration of solar radiation in the atmosphere in the Schumann-Runge wavelength region was based originally on laboratory cross section measurements using insufficient spectral resolution. Yoshino et al.<sup>98</sup> reported high resolution O<sub>2</sub> cross section measurements and band oscillator strengths of the (1,0)–(12,0) S-R bands in the wavelength range 179–202 nm at 300 K, obtaining the first set of results that were not limited by the instrument lineshape. Additional studies at other temperatures, wavelengths, and isotopic compositions have been carried out by Yoshino et al.,<sup>90,94–97</sup> Lewis et al.,<sup>51,52</sup> Cheung et al.,<sup>16,17</sup> and Chiu et al.<sup>21</sup> More recently, Yoshino et al.<sup>89</sup> reported cross sections of the S-R bands in the window region between the rotational lines for wavelengths between 180 and 195 nm; these measurements supersede the their earlier values reported in Yoshino et al.<sup>98</sup>

Absorption cross sections of the S-R continuum (130–175 nm) at room temperature were measured by Watanabe et al.,<sup>83</sup> Metzger and Cook,<sup>56</sup> and Ogawa and Ogawa.<sup>66</sup> Measurements of the temperature dependence were reported by Gibson et al.,<sup>30</sup> Hudson et al.,<sup>35</sup> Wang et al.,<sup>81</sup> Kanik et al.,<sup>43</sup> and Yoshino et al.<sup>101</sup>

Minschwaner et al.<sup>57</sup> have fit temperature dependent (130<T<500 K) O<sub>2</sub> cross sections between 175 and 204 nm with polynomial expressions, providing an accurate model of the Schumann-Runge band cross sections that incorporates the most recent laboratory data. Detailed photodissociation rates for the Herzberg continuum  $\lambda > 200$  nm were calculated by Nicolet and Kennes.<sup>61</sup> A parameterization in the Herzberg continuum was reported by Nicolet and Kennes.<sup>62</sup>

For parameterizations of the O<sub>2</sub> absorption in the Schumann-Runge bands used in atmospheric modeling calculations see Kockarts<sup>45</sup> and the review in WMO Report No. 16.<sup>86</sup> More recent work by Murtagh,<sup>59</sup> Nicolet and Kennes,<sup>63</sup> and Minschwaner et al.<sup>57</sup> incorporates results of the later laboratory measurements into efficient schemes for computing broadband transmission and photolysis rates. Transmission values obtained by Murtagh<sup>59</sup> agree well with the WMO<sup>86</sup> recommendations, although the high resolution calculations of Minschwaner et al.<sup>58</sup> differ with the WMO values by as much as 10–20% at some wavelengths.

Absorption cross section measurements in the region 240–300 nm were performed by Fally et al.<sup>28</sup> The different components of the spectrum, namely the discrete bands of the three Herzberg systems I, II, III (A, c, A' ← X), the Herzberg continuum, and the collision-induced Wulf bands were reported separately. The

Herzberg continuum cross sections at 240 nm are in good agreement with the values reported by Yoshino et al.<sup>88</sup> and Jenouvrier et al.<sup>40</sup> The absorption cross sections measured by Fally et al.<sup>28</sup> in the range 241–245 nm are entered in Table 4A-2. The absorption cross sections reported by Bogumil et al.<sup>13</sup> are roughly five times larger (at 241 nm) than those reported by Fally et al.<sup>28</sup> High resolution studies were performed by Yoshino et al.,<sup>91,99,100</sup> Huestis et al.,<sup>37</sup> Bao et al.,<sup>9</sup> and Slanger et al.<sup>76</sup> in the 242 to 248 nm range, where weak absorptions cross sections were reported for some vibrational bands in the Herzberg systems.

The O<sub>2</sub> cross section uncertainty factor is estimated to be 1.2 (1 $\sigma$ ) for both the Schumann-Runge bands and continuum regions of its spectrum.

*Photolysis Quantum yields and Product studies:* The overall quantum yield for photodissociation channel (1), O(<sup>3</sup>P) + O(<sup>3</sup>P), is unity,  $\Phi(1) = 1$ , for  $175 < \lambda < 242$  nm. Above the threshold for channel (2), O(<sup>3</sup>P) + O(<sup>1</sup>D), at 175 nm, Lee et al.<sup>47</sup> and Nee and Lee<sup>60</sup> determined the quantum yield of O(<sup>1</sup>D) to be unity. Thus,  $\Phi(2) = 1$ , in the wavelength range 139–175 nm. At 157 nm, both product channels (1) and (2) have been observed by Lin et al.,<sup>54</sup> with a relative yield for channel (1) of  $0.55 \pm 0.05$ . At wavelengths shorter than 139 nm Lee et al.<sup>47</sup> observed strong variations in  $\Phi(O^1D)$ , which was confirmed by Nee and Lee<sup>60</sup> (116–139 nm), Lee and Nee<sup>49</sup> (113–130 nm), and Lee and Nee<sup>50</sup> (105–113 nm). Lee et al.<sup>47</sup> reported  $\Phi(O^1D) = \Phi(2) = 0.44 \pm 0.05$  at the Lyman- $\alpha$  line (121.567 nm). Lacourrière et al.<sup>46</sup> determined the O(<sup>1</sup>D) yield across the entire Lyman- $\alpha$  profile from 121.2 to 121.9 nm at a spectral resolution of 0.0012 nm, and found  $\Phi(O^1D)$  to be strongly wavelength dependent in this window.  $\Phi(O^1D)$  varied from 1.0 at 121.35 nm through a minimum of 0.48 near 121.62 nm. A strong temperature dependence was found by Lewis et al.<sup>53</sup> with a minimum yield of 0.28 near 121.62 nm at 84 K.

	→ O( <sup>1</sup> S) + O <sub>2</sub> (a <sup>1</sup> Δ <sub>g</sub> )	610 kJ mol <sup>-1</sup>	196 nm	(8)

(Recommendation: 10-6, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections.* The O<sub>3</sub> absorption cross sections in the 200–790 nm region can be separated into four systems: the Hartley band (200–300 nm), the Huggins bands (300–370 nm), the Chappuis band (370–790 nm), and the Wulf bands extending towards longer wavelengths. The Hartley band is the strongest band and peaks around 255 nm. Although its overall shape is very smooth, there is residual vibrational structure in the region 250–260 nm. The Huggins band consists of a series of individual peaks and is marked with a drastic change of absorption cross sections (over more than five orders of magnitude) and strong temperature dependence. The Chappuis band is composed of a vibrational band progression superimposed on a continuous absorption in the visible region and is about a thousand times weaker than the Hartley band. The very weak near infrared part of the Chappuis band is clearly structured and corresponds to a different electronic transition (called the “Wulf bands”).

Photolysis of ozone in the Hartley system occurs predominantly via the two spin-allowed channels (1) and (5) (Ball et al.<sup>11</sup>) whereas channels (2), (3) and (4) are spin forbidden. Channels (2) and (4) have been identified from photolysis in the Huggins band (Silvente et al.<sup>64</sup> and Denzer et al.<sup>30</sup>).

For the three main bands in the 200–790 nm region, there have been many different measurements of the absorption spectrum and cross sections at various experimental (temperature and pressure) and instrumental conditions (resolution) during the last century as given in Table 4A-3. The available measurements can be organized into three groups: (A) measurements of absolute cross sections at single wavelengths (e.g. at the Hg resonance line at 253.65 nm), (B) measurements of absolute cross sections over broad spectral regions (typically covering a few hundred nm), (C) measurements of relative O<sub>3</sub> absorption spectra over broad spectral regions that have been scaled to absolute spectra using results from other studies (Type A or B), (D) measurements of the O<sub>3</sub> cross section at a single wavelength relative to the O<sub>3</sub> cross section at another wavelength.

Earlier reviews of the measured absorption cross sections were presented by Inn and Tanaka,<sup>42</sup> Ackermann,<sup>1</sup> Hudson,<sup>40</sup> Nicolet,<sup>55</sup> Brion et al.,<sup>21</sup> Steinfeld et al.,<sup>67</sup> Bacis et al.,<sup>9</sup> Matsumi and Kawasaki,<sup>49</sup> and the WMO Report No. 16,<sup>83</sup> which was the basis for the JPL-97-4 evaluation. Orphal<sup>59,60</sup> has recently critically reviewed the available laboratory measurements up to 2003, and the JPL 10-6 evaluation is partly based on that review. Relevant for that evaluation are the measurements of type B and C, particularly those studies whose data were digitally available (marked with an asterisk\*). Unfortunately, the recommended data set for the JPL-97-4 evaluation of Molina and Molina<sup>53</sup> was not considered in his review.

In the Hartley and Huggins bands (about 240–325 nm) there is generally very good agreement (better than 2–3%) between the data measured at room temperature (293–300 K) by Bass and Paur<sup>13</sup> and Paur and Bass,<sup>61</sup> Molina and Molina,<sup>53</sup> Freeman et al.,<sup>33</sup> Yoshino et al.,<sup>85</sup> the Reims-team (Daumont et al.,<sup>26</sup> Brion et al.,<sup>18</sup> Malicet et al.,<sup>46</sup> and Brion et al.<sup>17</sup>), Yoshino et al.,<sup>84</sup> the Bremen-team (Burrows et al.,<sup>24</sup> Voigt et al.,<sup>82</sup> and Bogumil et al.,<sup>16</sup> Gorshelev et al.<sup>36</sup>), Petersen et al.,<sup>62</sup> and Viallon et al.<sup>78</sup> The older data by Ny and Choong,<sup>57</sup> Inn and Tanaka,<sup>41</sup> and Vigroux<sup>79</sup> are about 8% greater than the data of Molina and Molina.<sup>53</sup> The vibrational structure between 240 and 270 nm was observed in most studies, except those of Inn and Tanaka,<sup>41</sup> DeMore and Raper,<sup>29</sup> Davenport,<sup>28</sup> and Astholz et al.,<sup>7</sup> who used lower resolution instruments.

Measurements of absorption cross sections in the shorter wavelength VUV region were performed by Tanaka et al.,<sup>74</sup> Ogawa and Cook,<sup>58</sup> and Mason et al.<sup>47</sup> At the Lyman- $\alpha$  wavelength, 121.567 nm, an absorption cross section of  $2.32 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup> was cited in the review by Ackermann.<sup>1</sup> Ogawa and Cook<sup>58</sup> measured  $2.28 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup> whereas Mason et al.<sup>47</sup> reported  $2.99 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup>. The latter more recent value is recommended and entered in Table 4A-4.

A comparison of the O<sub>3</sub> cross-sections at the Hg-line wavelength 253.7 nm was performed by Orphal<sup>59,60</sup> involving 13 absolute measurements and provided a mean value of  $(114.1 \pm 0.9) \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup>. Viallon et al.<sup>78</sup> has since reported a cross section value of  $(112.7 \pm 0.97) \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup>. The temperature dependence of the cross sections at 253.7 nm has been measured by Barnes and Mauersberger<sup>12</sup> between 195 and 351 K and by Malicet et al.<sup>45</sup> at 229 and 295 K. It has to be noted that the data of Bass and Paur<sup>13</sup> and Paur and Bass<sup>61</sup> are normalized to the absolute value  $114.7 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> at 253.7 nm and 295 K measured by Hearn.<sup>39</sup> In the range 230–260 nm, the data of the Reims-team (Daumont-Brion-Malicet-Brion) are generally lower (up to 2.5%) than the data of Molina and Molina,<sup>53</sup> Bass and Paur,<sup>13</sup> and the Bremen-team (Burrows-Voigt-Bogumil-Gorshelev-Serdyuchenko). Furthermore, the data of Voigt et al.<sup>82</sup> show a strong baseline shift below 255 nm and in the range 310–320 nm; in addition, the spectra are very noisy in the Hartley band maximum. The data of Bogumil et al.<sup>15</sup> contain periodic artifacts on the order of 0.5–1.0% in the range 240–270 nm and a stray light feature around 305 nm on the order of 2%.

Below 225 nm the room temperature cross sections of Molina and Molina,<sup>53</sup> DeMore and Raper,<sup>29</sup> and the Reims-team (Daumont-Brion-Malicet) agree within 1–2%, but are 2–5% larger than the measurements of

Yoshino et al.<sup>84</sup> Other reported values measured by Ny and Choong,<sup>57</sup> Inn and Tanaka,<sup>41</sup> Astholz et al.,<sup>7</sup> and Griggs<sup>37</sup> differ up to 15%.

In the Huggins bands (310–350 nm) the studies differ in spectral resolution, which is mostly relevant only to atmospheric remote sensing. At wavelengths larger than 310 nm the vibrational structure becomes pronounced. In the range 310–340 nm, the agreement between the different studies is rather good (about 2%) for the data of Bass and Paur,<sup>13</sup> the Reims-team (Daumont-Brion-Malicet-Brion), Burrows et al.,<sup>24</sup> Gorshelev et al.,<sup>36</sup> and Serdyuchenko et al.,<sup>63</sup> although important differences (up to 13%) due to wavelength shifts and spectral resolution are reported by Orphal.<sup>59,60</sup> The data of Bass and Paur<sup>13</sup> and of the Reims-team (Daumont-Brion-Malicet-Brion) show wavelength shifts of more than 0.02 nm. The data of Voigt et al.<sup>82</sup> and Bogumil et al.<sup>16</sup> contain systematic baseline drifts. Above 312 nm, the data of Molina and Molina,<sup>53</sup> which are listed every 0.5 nm up to 350 nm, occasionally miss the maxima and minima of the peaks. The reported values by Cacciani et al.<sup>25</sup> are typically 5–8% lower than the values of Molina and Molina<sup>53</sup> in the range 339–355 nm.

The O<sub>3</sub> absorption cross sections in the 350–450 nm region between the Huggins and Chappuis bands are very small and the available measurements of absolute values scatter significantly. They have been measured by Brion et al.,<sup>17</sup> the Bremen team (Burrows-Voigt-Bogumil-Gorshelev-Serdyuchenko), Fuchs et al. (at 404 nm),<sup>35</sup> and Axson et al.<sup>8</sup> At the minimum near 378 nm, the reported absolute cross sections at 298 K vary between  $5 \times 10^{-23}$  cm<sup>2</sup> molecule<sup>-1</sup> from Voigt et al.<sup>82</sup> and  $5 \times 10^{-24}$  cm<sup>2</sup> molecule<sup>-1</sup> from Brion et al.<sup>17</sup>

Absorption cross section measurements of the Chappuis band of O<sub>3</sub> in the wavelength range 450–750 nm have been reported by Burkholder and Talukdar,<sup>23</sup> Brion et al.,<sup>17</sup> the Bremen team (Burrows-Voigt-Bogumil-Gorshelev-Serdyuchenko), El Helou et al.,<sup>31</sup> and at single wavelengths by Hearn,<sup>39</sup> Anderson and Mauersberger,<sup>5</sup> Anderson et al.,<sup>4</sup> and Enami et al.<sup>32</sup> At the peak of the Chappuis band near 602 nm, the values agree within a few percent, although the data of the Bremen-team (Burrows-Voigt-Bogumil) are consistently larger than those of Brion et al.<sup>17</sup> (by 2%) and Burkholder and Talukdar<sup>23</sup> (by 4%) (the latter data are scaled using the measurements of Anderson and Mauersberger<sup>5</sup>). Note that there are pronounced deviations of data from Burkholder and Talukdar<sup>23</sup> in the region 425–490 nm. The older values of Vassy and Vassy,<sup>77</sup> Vigroux,<sup>79</sup> Inn and Tanaka,<sup>41</sup> Griggs,<sup>37</sup> and Amoruso et al.<sup>3</sup> deviate up to 20%.

Absorption cross sections in the Wulf band region (wavelength >750 nm) have been reported by Anderson et al.,<sup>4</sup> Burkholder and Talukdar,<sup>23</sup> the Bremen-team (Burrows-Voigt-Bogumil-Gorshelev-Serdyuchenko), Enami et al.,<sup>32</sup> and El Helou et al.<sup>31</sup> The data measured at room temperature by the latter group are in excellent agreement (within 0.25%) with those of Anderson et al.<sup>4</sup>

The temperature dependence of the O<sub>3</sub> cross sections has also been studied by several of the groups mentioned above and tabulated in Table 4A-3. In the critical review, Orphal<sup>59,60</sup> calculated and compared the integrated cross sections for 5 temperatures in the range 203–295 K in the different spectral regions of the O<sub>3</sub> spectrum. At all temperatures the agreement of the integrated cross sections in the Hartley band is better than 2% and less good agreement in the Chappuis band (4%). In particular, the integrated cross sections of Burkholder and Talukdar<sup>23</sup> lie systematically below the other measurements by about 3% and the data of Burrows et al.<sup>24</sup> are always higher by 2%. In the Huggins bands and the blue tail of the Chappuis band the integrated cross sections scatter by several percent (up to 5%), indicating systematic differences between the available data. The Hartley band integrated cross sections remain constant in the temperature range 203–293 K within the experimental uncertainties. The integrated cross sections in the Huggins bands decrease by more than 30% between 298 K and 203 K and the differential cross sections of the bands increase significantly.

In the Hartley band most studies report a slight (0.9–1.6%) increase of the cross section below 260 nm between room temperature and low temperatures 202–298 K, while Yoshino et al.<sup>84</sup> concluded that the temperature effect is negligible. Above 260 nm the cross section decreases significantly at lower temperatures. This effect is due to the changing populations of the various vibrational and rotational quantum states of ozone and has been analyzed by Simons et al.<sup>65</sup> The cross section values are not linearly proportional to the temperature; instead the effect is larger at the maxima than it is at the minima of the spectral features.

The absorption cross sections in the Huggins bands (310–350 nm) of O<sub>3</sub> decrease strongly with decreasing temperatures. Additionally, they depend on instrumental line shape and differences in wavelength calibration so that discrepancies up to 20% at the lowest temperatures are observed between the various studies. Comparison of the spectra obtained in the temperature range 220–229 K show good agreement (~3% at 325 nm, ~5% at 340 nm) with the data of Bass and Paur,<sup>13</sup> Molina and Molina,<sup>53</sup> the Brion team (Daumont-Brion-Malicet-Brion), and Burrows et al.<sup>24</sup> The data of Voigt et al.<sup>82</sup> and Bogumil et al.<sup>16</sup> display sudden baseline jumps and are consistently lower than the other cited data sets. Voigt et al.<sup>82</sup> observed in the region

335–380 nm the presence of “hot bands”, which disappear with decreasing temperature, and “cold bands”, which become more pronounced at lower temperatures.

In the Chappuis band, the available cross sections agree in showing a very small increase (1%) with decreasing temperature in the wavelength range 550–560 nm. However there is strong disagreement in the relative temperature dependence of the cross sections in the wings (400–550 nm and 650–790 nm) of the Chappuis band. Burkholder and Talukdar<sup>23</sup> report a decrease from 4% at 520 nm to 40% at 420 nm between 298 and 220 K, while Burrows et al.<sup>24</sup> observe a decrease at 420 nm to 70% at 221 K, and Bogumil et al.<sup>16</sup> a decrease of 20% at 223 K. These discrepancies could be due to baseline problems in the different measurements. It was also noted by the Bremen-team (Burrows-Voigt-Bogumil-Serdyuchenko) that in the wings the differential cross sections increase up to 10% between 298 and 203 K. In addition, the band structures between 400 and 500 nm shift toward shorter wavelengths with decreasing temperature. El Helou et al.<sup>31</sup> found the cross sections of the Wulf bands to be highly temperature dependent, increasing up to 91% upon reducing the temperature to 150 K.

Three different models have been proposed to reproduce the temperature dependence of the O<sub>3</sub> cross sections in the entire ultraviolet and visible regions within the experimental uncertainties. The first model was developed for the Hartley band by Adler-Golden<sup>2</sup> and uses an exponential function. The second model, developed by Bass and Paur,<sup>13</sup> uses a quadratic polynomial to be applied in the Hartley and Huggins bands. The third model of Voigt et al.<sup>82</sup> uses a double exponential function. The accuracy of the models was checked by Orphal,<sup>59,60</sup> who concluded that the experimental data are better reproduced using a quadratic polynomial.

The pressure dependence of the O<sub>3</sub> absorption cross sections was investigated by Hearn<sup>39</sup> in the Hartley band and by Voigt et al.<sup>82</sup> in the entire spectral region 240–790 nm. Both groups did not find experimental or theoretical support for pressure dependence, although Voigt et al.<sup>82</sup> proposed that temperature variations of the cross sections around 400 nm might be due to the formation of a weakly bound O<sub>2</sub>-O<sub>3</sub> complex.

The recommended absorption cross sections are listed in Table 4A-4, averaged over atmospheric intervals at 218 K and at room temperature (293–298 K). It has to be noted that cross sections are listed over 500 cm<sup>-1</sup> intervals in the region 185–300 nm, over 1 nm intervals in the region 300–321 nm, over 2 nm intervals in the region 321.5–326.5 nm, and over 5 nm intervals in the region 330–825 nm. The 218 K values measured by the Reims-team (Daumont-Brion-Malicet-Brion) are only listed for the range 196–340 nm. The room temperature data were selected for the range 185–233 nm from the data of Molina and Molina,<sup>53</sup> for the range 323–310 nm from Burrows et al.,<sup>24</sup> and for the range 310–825 nm from the Reims team (Daumont-Brion-Malicet-Brion).

The uncertainty factor for the room temperature O<sub>3</sub> cross section is estimated to be 1.02 (1 $\sigma$ ) near the peaks of the Hartley and Chappuis bands and the strong Huggins peaks. The estimated uncertainty in the 360–400 nm region is greater, 1.1 (1 $\sigma$ ), primarily due to the spread in the available data sets.

**Table 4A-4. Recommended Absorption Cross Sections of O<sub>3</sub> at 218 and 293–298 K**

Brion et al.<sup>17</sup>

*Photolysis Quantum Yields and Product Studies.* The recommendation for the O(<sup>1</sup>D) quantum yield from ozone photolysis as a function of wavelength and temperature, based on the review of Matsumi et al.,<sup>48</sup> is given by the expression (Eqn 4-1)

$$\Phi(\lambda, T) = \left( \frac{q_1}{q_1 + q_2} \right) \times A_1 \times \exp \left\{ - \left( \frac{X_1 - \lambda}{\omega_1} \right)^4 \right\} + \left( \frac{q_2}{q_1 + q_2} \right) \times A_2 \times \left( \frac{T}{300} \right)^2 \times \exp \left\{ - \left( \frac{X_2 - \lambda}{\omega_2} \right)^2 \right\}$$

$$+ A_3 \times \left( \frac{T}{300} \right)^{1.5} \times \exp \left\{ - \left( \frac{X_3 - \lambda}{\omega_3} \right)^2 \right\} + c \quad \text{Eqn 4-1}$$

where  $q_i = \exp\left(-\frac{v_i}{RT}\right)$  and  $X_{1-3}$ ,  $A_{1-3}$ ,  $\omega_{1-3}$ ,  $v_{1-2}$  and  $c$  are best-fit parameters given in Table 4A-5,  $\lambda$  is in nm,  $T$  is in K, and  $R = 0.695 \text{ (cm}^{-1} \text{ K}^{-1})$ . The parameter  $c$  is assumed to be temperature and wavelength independent. This expression is valid only for the wavelength range 306–328 nm and temperature range 200–320 K.

**Table 4A-5. Parameters for the Calculation of O(<sup>1</sup>D) Quantum Yields**

Parameter	i = 1	i = 2	i = 3
X <sub>i</sub> (nm)	304.225	314.957	310.737
ω <sub>i</sub> (nm)	5.576	6.601	2.187
A <sub>i</sub>	0.8036	8.9061	0.1192
v <sub>i</sub> (cm <sup>-1</sup> )	0	825.518	—
c	0.0765	—	—

At room temperature (298 K) the uncertainties of the quantum yield values calculated with the above expression are estimated to be  $\pm 10\%$  ( $1\sigma$ ) for  $\Phi(\lambda, 298 \text{ K}) \geq 0.4$ , while the uncertainties are estimated to be  $\pm 0.04$  for  $\Phi(\lambda, 298 \text{ K}) < 0.4$ . At temperatures other than room temperature, the uncertainties are estimated to be  $\pm 15\%$  for  $\Phi(\lambda, T) \geq 0.4$  and  $\pm 0.06$  for  $\Phi(\lambda, T) < 0.4$ .

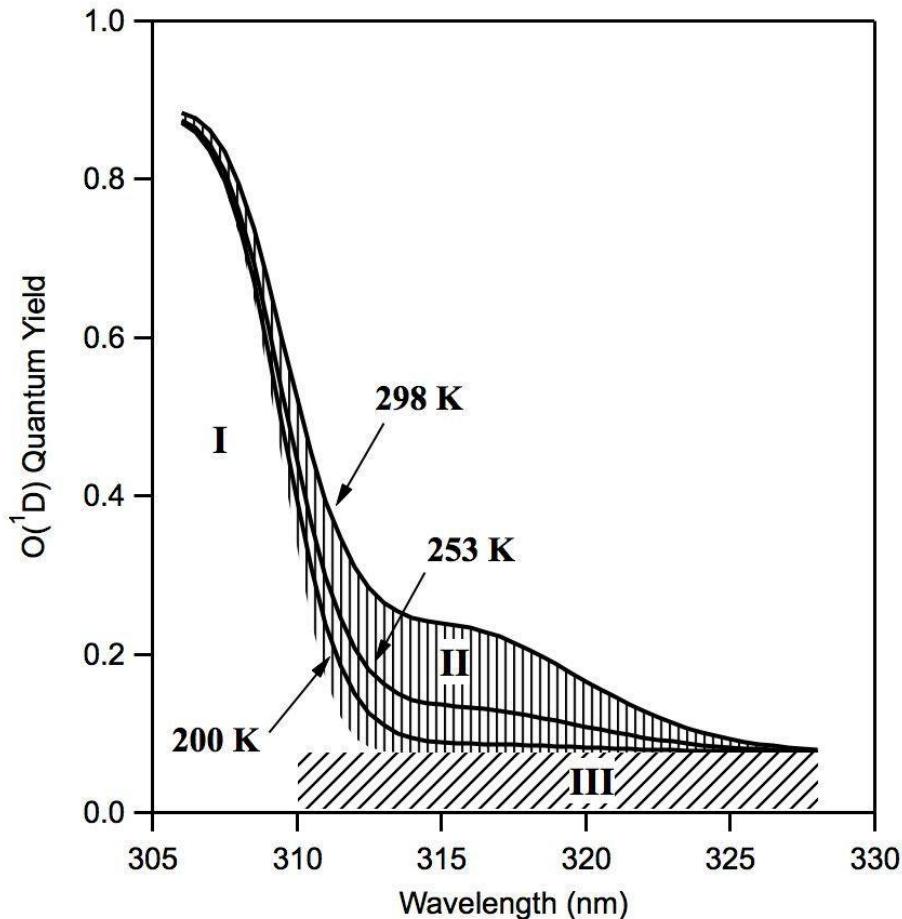

In the wavelength range 329–340 nm the recommended value of  $\Phi(O^{1D}) = 0.08 \pm 0.04$ , independent of temperature. For  $\lambda > 340 \text{ nm}$ , the quantum yield may be non-zero but no recommendation is made. For the wavelength range 220–305 nm, the recommended O(<sup>1</sup>D) quantum yield is 0.90, independent of temperature, based on the study by Takahashi et al.<sup>69</sup> and the review by Matsumi and Kawasaki.<sup>49</sup> The quantum yield for O(<sup>1</sup>D) formation in the range 193–225 nm was measured by Nishida et al.<sup>56</sup> who found that the O(<sup>1</sup>D) yield decreased from  $0.90 \pm 0.12$  (225 nm) to  $0.48 \pm 0.03$  (193 nm). A simple expression in the wavelength range 193–225 nm was derived

$$\Phi_{O^{1D}}(\lambda) = 1.37 \times 10^{-2} \lambda - 2.16$$

Matsumi et al.<sup>48</sup> derived the recommended values for the temperature and wavelength dependences of  $\Phi(O^{1D})$  using the following procedure: the measured O(<sup>1</sup>D) quantum yields at 298 K between 306 and 328 nm from eight studies (Talukdar et al.,<sup>73</sup> Takahashi et al.,<sup>70</sup> Ball et al.,<sup>10</sup> Armerding et al.,<sup>6</sup> Bauer et al.,<sup>14</sup> which superseded the data of Silvente et al.<sup>64</sup> from the same group, Brock and Watson,<sup>22</sup> Trolier and Wiesenfeld,<sup>75</sup> and Smith et al.<sup>66</sup> were normalized using  $\Phi(O^{1D}) = 0.79$  at 308 nm. This value was derived from the studies listed in Table 1 of Matsumi et al.<sup>48</sup> The renormalized data were then averaged. The wavelength dependence quantum yield data at various temperatures reported by Talukdar et al.,<sup>72,73</sup> Takahashi et al.,<sup>70</sup> Hancock and Hofzumahaus<sup>38</sup> (this includes all the data from the Oxford group), Bauer et al.,<sup>14</sup> and Smith et al.<sup>66</sup> were normalized to the value at 308 nm given above. These normalized data were used to obtain the best fit parameters for Eqn. 4-1 for the wavelength range 306–328 nm and temperature range 200–320 K. Because of the large number of studies upon which the 298 K evaluation is based, the averaged 298 K data were given a larger weight in the fitting procedure than the data at other temperatures. The recommended O(<sup>1</sup>D) quantum yields calculated from Eqn. 4-1 using the fitting parameters given in Table 4A-5 are shown in Figure 4-1 for 200, 253 and 298 K in the wavelength range 306–328 nm (solid lines).

Products and yields from O<sub>3</sub> photodissociation at 157.6 nm were measured by Taherian and Slanger.<sup>68</sup> The primary atomic oxygen yield was measured to be  $1.90 \pm 0.30$ , of which 71% is O(<sup>3</sup>P) and 29% O(<sup>1</sup>D). Turnipseed et al.<sup>76</sup> measured the quantum yield for O(<sup>3</sup>P) and O(<sup>1</sup>D) formation from 193 nm photolysis to be  $0.57 \pm 0.14$  and  $0.46 \pm 0.29$ , respectively, and at 222 nm they observed a quantum yield of  $0.13 \pm 0.02$  for O(<sup>3</sup>P) and  $0.87 \pm 0.04$  for O(<sup>1</sup>D).

Lee et al.<sup>44</sup> reported an upper limit of  $<0.1\%$  for the quantum yield for the formation of O(<sup>1</sup>S) via channel (8) in the 170–240 nm range. Takahashi et al.<sup>71</sup> measured the quantum yield of O(<sup>1</sup>S) formation to be  $(2.5 \pm 1.1) \times 10^{-3}$  in the 193 nm photolysis of O<sub>3</sub>, while Nakayama et al.<sup>54</sup> reported  $(1.4 \pm 0.4) \times 10^{-4}$  and  $(5 \pm 3) \times 10^{-5}$  for the O(<sup>1</sup>S) formation at 215 and 220 nm, respectively.

**Figure 4A-1.** Recommended O(^1D) quantum yields calculated from Eqn. 4-1 using the fitting parameters given in Table 4A-5 for 200, 253 and 298 K in the wavelength range 306–328 nm (solid lines), based on Matsumi et al.<sup>48</sup> Contributions from different photolysis channels are indicated: region I corresponds to O(^1D) formed via channel (5), O(^1D) + O<sub>2</sub>(a<sup>1</sup>Δ<sub>g</sub>), region II (vertical hatching) represents the contribution of the hot-band excitation process via channel (5), while region III (diagonal hatching) corresponds to the contribution of O(^1D) via the spin-forbidden channel (4), O(^1D) + O<sub>2</sub>(X<sup>3</sup>Σ<sub>g</sub><sup>-</sup>).

## SECTION 4B. HO<sub>x</sub> PHOTOCHEMISTRY

### B1. HO<sub>2</sub> (hydroperoxyl radical)

[Back to Index](#)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

*Absorption Cross Sections:* UV absorption cross sections of HO<sub>2</sub> in the wavelength range 190–260 nm have been measured at room temperature by Paukert and Johnston,<sup>12</sup> Hochanadel et al.,<sup>4</sup> Cox and Burrows,<sup>1</sup> McAdam et al.,<sup>10</sup> Kurylo et al.,<sup>5</sup> Moortgat et al.,<sup>11</sup> Dagaut and Kurylo,<sup>3</sup> Lightfoot and Jemi-Alade,<sup>8</sup> who measured the cross sections at temperatures up to 777 K, Crowley et al.,<sup>2</sup> Maricq and Szente,<sup>9</sup> Roehl et al.,<sup>13</sup> and Sander et al.<sup>14</sup> The HO<sub>2</sub> absorption cross section studies have been evaluated in reviews by Lightfoot et al.,<sup>7</sup> Wallington et al.,<sup>16</sup> and Tyndall et al.<sup>15</sup> Discrepancies in the shape of the HO<sub>2</sub> spectrum and its absolute cross sections, particularly around 200 nm, exist among the available studies. Tyndall et al.<sup>15</sup> recommend absolute HO<sub>2</sub> cross sections based on a comparison of absorption cross sections for HO<sub>2</sub>, CH<sub>3</sub>O<sub>2</sub> and C<sub>2</sub>H<sub>5</sub>O<sub>2</sub> at 240 nm obtained by Roehl et al., Lightfoot and Jemi-Alade, and Maricq and Szente combined with the measurements by Crowley et al.<sup>2</sup> at 240 nm. Tyndall et al.<sup>15</sup> used the expression

$$\sigma = \frac{\sigma_{med}}{\left(1 - \frac{b}{\nu}\right)} \exp \left\{ -a \left[ \ln \frac{(\nu - b)}{(\nu_{med} - b)} \right]^2 \right\}$$

where  $\sigma_{med} = 1.64 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ ,  $a = 4.91$ ,  $b = 30612 \text{ cm}^{-1}$  and  $\nu_{med} = 50260 \text{ cm}^{-1}$  that reproduces the HO<sub>2</sub> spectrum over the wavelength range 190–250 nm. They recommend that the spectrum be treated as temperature independent over the range 200–300 K. The recommended HO<sub>2</sub> cross sections in Table 4B-1 are taken from the Tyndall et al.<sup>15</sup> review.

*Photolysis Quantum Yield and Product Studies:* Lee<sup>6</sup> detected O(<sup>1</sup>D) as a primary photodissociation product of HO<sub>2</sub> at 193 and 248 nm with a quantum yield that is about 15 times larger at the longer wavelength. An absolute quantum yield for O(<sup>1</sup>D) production has not been reported.

**Table 4B-1. Recommended Absorption Cross Sections of HO<sub>2</sub> at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )
190	368
195	402
200	423
205	427
210	415
215	385
220	341
225	288
230	230
235	173
240	122
245	79.7
250	48.0
255	26.3
260	12.9

	→ O( <sup>3</sup> P) + H + H	927 kJ mol <sup>-1</sup>	129 nm	(5)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV absorption spectrum of water vapor can be divided up into four main regions: (i) a broad continuum at wavelengths 145–190 nm with a maximum around 165 nm and the cross sections falling off rapidly toward longer wavelengths; (ii) a second continuum centered around 128 nm, which shows some diffuse vibrational structure; (iii) between 124–100 nm the absorption spectrum is dominated by progressions of sharp structured rovibronic peaks associated with Rydberg transitions; (iv) below 100 nm the spectrum is also a continuum consisting of two diffuse bands with maxima near 90 and 65 nm. In the atmosphere, water vapor is photodissociated mainly by the solar Lyman-α line (121.567 nm). The absorption cross sections and the photochemistry of water vapor were reviewed by Hudson,<sup>22,23</sup> Hudson and Kiefer,<sup>24</sup> Calvert and Pitts,<sup>6</sup> and Okabe.<sup>38</sup> Table 4-B2 summarizes the studies performed since 1950.

The cross sections in the VUV band in the range 6 to 110 nm measured by Katayama et al.,<sup>26</sup> Gürtler et al.,<sup>19</sup> Phillips et al.,<sup>40</sup> Tan et al.,<sup>44</sup> Lee and Suto,<sup>30</sup> Chan et al.<sup>9</sup> are in good agreement, whereas the data of Wainfan

et al.,<sup>50</sup> Metzger and Cook,<sup>34</sup> de Reilhac and Damany,<sup>15</sup> Bennett et al.,<sup>3</sup> and Branton and Brion<sup>4</sup> show substantial deviations.

In the strong structured region between 100 and 125 nm, cross sections were measured at low resolution by Watanabe and Zelikoff,<sup>52</sup> Watanabe and Jursa,<sup>51</sup> Tan et al.,<sup>44</sup> Lee,<sup>29</sup> Lee and Suto,<sup>30</sup> Chan et al.,<sup>9</sup> and at high resolution by Gürler et al.,<sup>19</sup> Lewis et al.,<sup>31</sup> The Harvard-Smithsonian Center for Astrophysics,<sup>1</sup> Fillion et al.,<sup>18</sup> and Mota et al.<sup>36</sup>

Absorption cross sections were reported at the Lyman- $\alpha$  wavelength, 121.567 nm, in units  $10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ , to be  $1.44 \pm 0.04$  by Watanabe and Zelikoff,<sup>52</sup>  $1.4 \pm 0.3$  by Nicolet,<sup>37</sup>  $1.5 \pm 0.1$  by Gürler et al.,<sup>19</sup>  $1.55 \pm 0.1$  by Lewis et al.,<sup>31</sup>  $1.59 \pm 0.1$  by Kley,<sup>27</sup>  $1.42 \pm 0.1$  by Lee,<sup>29</sup>  $1.3 \pm 0.05$  by Chan et al.,<sup>9</sup>  $1.4 \pm 0.03$  by Yoshino et al.,<sup>54</sup>  $1.6 \pm 0.1$  by Brownsword et al.,<sup>5</sup> and  $1.6 \pm 0.1$  by Vatsa and Volpp.<sup>49</sup> An average value  $(1.48 \pm 0.10) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  for the absorption cross section at the Lyman- $\alpha$  wavelength 121.567 nm is recommended.

In the weak structured region between 125 and 140 nm, measurements at low resolution were reported by Watanabe and Zelikoff,<sup>52</sup> Laufer and McNesby,<sup>28</sup> Schürgers and Welge,<sup>41</sup> Branton and Brion,<sup>4</sup> Tan et al.,<sup>44</sup> Lee,<sup>29</sup> Lee and Suto,<sup>30</sup> Chan et al.,<sup>9</sup> and at high resolution by Yoshino et al.,<sup>54</sup> Cheng et al.,<sup>10</sup> and Mota et al.<sup>36</sup>

In the broad continuum at long wavelengths 145–190 nm, measurements at low resolution were performed by Wilkinson and Johnston,<sup>53</sup> Watanabe and Zelikoff,<sup>52</sup> Harrison et al.,<sup>20</sup> Thompson et al.,<sup>47</sup> Laufer and McNesby,<sup>28</sup> Schürgers and Welge,<sup>41</sup> Branton and Brion,<sup>4</sup> Tan et al.,<sup>44</sup> Lee and Suto,<sup>30</sup> Chan et al.,<sup>9</sup> and at high resolution by Yoshino et al.,<sup>54</sup> Chung et al.,<sup>12</sup> and Mota et al.<sup>36</sup>

In the tail of the absorption band in the wavelength range 185–200 nm, measurements were reported by Cantrell et al.,<sup>8</sup> Creasey et al.,<sup>14</sup> Chung et al.,<sup>12</sup> Parkinson and Yoshino,<sup>39</sup> and Mota et al.<sup>36</sup> At the 184.94 nm Hg line, absorption cross sections were measured, in units  $10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ , to be 7.8 by DeMore,<sup>16</sup>  $7.14 \pm 0.2$  by Cantrell et al.,<sup>8</sup>  $7.22 \pm 0.22$  by Creasey et al.,<sup>14</sup>  $10.1 \pm 0.1$  by Yoshino et al.,<sup>54</sup> 7.0 by Hofzumahaus et al.,<sup>21</sup> and 7.3 (a value measured by J. Crowley, cited by Hofzumahaus et al.<sup>21</sup>). Based on the latter studies, the recommended value for the absorption cross section at 184.94 nm is  $(7.1 \pm 0.2) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  at 298 K.

High resolution spectra of water vapor and complete sets of line parameters have been measured in the visible region by Camy-Peyret et al.<sup>7</sup> (369–606 nm), Mandin et al.<sup>32</sup> (606–758 nm), Fally et al.<sup>17</sup> (385–769 nm), Coheur et al.<sup>13</sup> (385–769 nm), and for H<sub>2</sub><sup>18</sup>O by Tanaka et al.<sup>46</sup> (584–689 nm), and Tanaka et al.<sup>45</sup> (606–689 nm); in the near infrared by Mérienne et al.<sup>33</sup> (769–1081 nm), Aldener et al.<sup>2</sup> (926–952 nm), and Kassi et al.<sup>25</sup> (747–752 nm).

The recommended absorption cross sections listed in Table 4B-3 are taken from Yoshino et al.<sup>54</sup> for the range 121–182 nm, from Cantrell et al.<sup>8</sup> for the range 183–191 nm, and from the interpolated data of Parkinson and Yoshino<sup>39</sup> for the range 192–198 nm.

*Photolysis Quantum Yield and Product Studies:* Stief et al.<sup>43</sup> reported a relative quantum yield of process (2)  $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] = 0.89$  and process (3)  $\Phi_3[\text{H}_2 + \text{O}^1\text{D}] = 0.11$  for the wavelength interval 105–145 nm, and  $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] \geq 0.99$  and  $\Phi_3[\text{H}_2 + \text{O}^1\text{D}] \leq 0.01$  for the interval 145–185 nm. Lee<sup>29</sup> measured the quantum yield of the emission of OH(A<sup>2</sup> $\Sigma^+$ ) → OH(X<sup>2</sup> $\Pi$ ) produced in process (4), varying between 2 and 11% in the wavelength range 105–135 nm. The quantum yields show a maximum of 11% at 130 nm, decreasing slowly with decreasing wavelengths. Ung<sup>48</sup> measured the relative quantum yields  $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] = 0.92$  and  $\Phi_3[\text{H}_2 + \text{O}^1\text{D}] = 0.08$  for the photolysis at 147 nm. At the Lyman- $\alpha$  wavelength (121.567 nm) a quantum yield for H atoms,  $\Phi_{\text{H}}$ , of 1.02 was determined by Slanger and Black.<sup>42</sup> They also measured a quantum yield for processes (2) + (4),  $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] + \Phi_4[\text{OH}(\text{A}^2\Sigma^+) + \text{H}]$ , of 0.78, for process (3),  $\Phi_3[\text{O}^1\text{D} + \text{H}_2]$ , of 0.10, and for process (5),  $\Phi_5[\text{O}^3\text{P} + \text{H} + \text{H}]$ , of 0.12. Chou et al.<sup>11</sup> photolyzed HTO at 174 nm and estimated  $\Phi_1 \leq 0.003$  for the formation of HT + O(<sup>3</sup>P) and  $\Phi_2 \sim 1$  for the processes leading to H + OT and T + OH. Mordaunt et al.<sup>35</sup> determined the absolute branching for the photodissociation channels at 121.567 nm as  $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] = 0.64$ ,  $\Phi_3[\text{O}^1\text{D} + \text{H}_2] = 0.11$ ,  $\Phi_4[\text{OH}(\text{A}^2\Sigma^+) + \text{H}] = 0.14$ , and  $\Phi_5[\text{O}^3\text{P} + \text{H} + \text{H}] = 0.11$ .

### B3. H<sub>2</sub>O<sub>2</sub> (hydrogen peroxide)

[Back to Index](#)

H <sub>2</sub> O <sub>2</sub> + hν → OH + OH	215 kJ mol <sup>-1</sup>	557 nm	(1)
→ H <sub>2</sub> O + O( <sup>1</sup> D)	333 kJ mol <sup>-1</sup>	359 nm	(2)
→ H + HO <sub>2</sub>	369 kJ mol <sup>-1</sup>	324 nm	(3)

(Recommendation: 90-1, Note: 15-10, Evaluated: 15-10)

**Absorption Cross Sections:** Absorption cross sections of hydrogen peroxide, H<sub>2</sub>O<sub>2</sub>, have been reported by a number of groups as summarized in Table 4B-4. The H<sub>2</sub>O<sub>2</sub> spectrum is continuous and the absorption cross sections decrease monotonically from 180 nm toward longer wavelengths. The cross section data from the studies performed after 1972 at wavelengths <350 nm are in reasonable agreement. Studies prior to 1977 are not considered for the recommendation. Nicovich and Wine<sup>11</sup> measured cross sections relative to the absolute values at 202.6 nm,  $\sigma = 4.32 \times 10^{-19}$  cm<sup>2</sup>, and 228.8 nm,  $\sigma = 1.86 \times 10^{-19}$  cm<sup>2</sup>, recommended in DeMore et al.<sup>1</sup> Knight et al.<sup>7</sup> normalized their spectra to the spectra of Nicovich and Wine<sup>11</sup> between 250 nm and 280 nm. The spectra measured by Knight et al.<sup>7</sup> at  $\lambda > 290$  nm are in excellent agreement with those reported by Nicovich and Wine<sup>11</sup> at all the temperatures studied. Kahan et al.<sup>6</sup> measured the absorption spectrum at 297 K between 353 and 410 nm, i.e., longer wavelengths than in previous studies, and quantified the spectrum using online absorption measurements at 213.9 nm (Zn line). Their absolute cross sections show a significant discontinuity with the recommended spectrum at shorter wavelengths. The Kahan et al.

study demonstrates that H<sub>2</sub>O<sub>2</sub> absorbs at the longer wavelengths and would contribute to the atmospheric photolysis loss of H<sub>2</sub>O<sub>2</sub>. However, due to the apparent disagreement with the previous absolute spectrum measurements at shorter wavelengths, a recommendation in this wavelength region is not given. The recommended 2 $\sigma$  uncertainty factors are 1.1 for the wavelength range 190 to 300 nm and 1.25 for the wavelength range 300 to 350 nm.

Vatsa and Volpp<sup>21</sup> measured the Lyman- $\alpha$  (121.567 nm) absorption cross section to be  $9.8 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup>, which is recommended. Primarily because there is only a single study at Lyman- $\alpha$  rather large uncertainty factor of 1.4 is recommended.

**Table 4B-4. Summary of H<sub>2</sub>O<sub>2</sub> Absorption Cross Section Studies**

Study	Year	Wavelength Range (nm)	Temperature (K)
Urey et al. <sup>17</sup>	1929	215–275	298
Fergusson et al. <sup>2</sup>	1936	220–290	298
Holt et al. <sup>5</sup>	1948	155–220	298
Schumb et al. <sup>14</sup>	1955	200–400	298
Schürgers and Welge <sup>15</sup>	1968	125–200	298
Troe <sup>16</sup>	1969	220–290	300
Hochenadel et al. <sup>4</sup>	1972	185–260	298
Molina et al. <sup>10</sup>	1977	210–350	296
Lin et al. <sup>8</sup>	1978	195–350	296
Molina and Molina <sup>9</sup>	1981	190–350	298
Nicovich and Wine <sup>11</sup>	1988	193–350	296, 285–381
Vaghjiani and Ravishankara <sup>18</sup>	1989	210–345	297
Vatsa and Volpp <sup>21</sup>	2001	121.567	300
Knight et al. <sup>7</sup>	2002	250–350	273, 296, 343
Kahan et al. <sup>6</sup>	2012	353–410	297

The recommended 298 K absorption cross section values for wavelengths <260 nm in Table 4B-5 are the mean of the data from Lin et al.,<sup>8</sup> Molina and Molina,<sup>9</sup> Nicovich and Wine,<sup>11</sup> and Vaghjiani and Ravishankara.<sup>18</sup> Molina and Molina<sup>9</sup> supersedes the results of Molina et al.<sup>10</sup>

The temperature dependence of the absorption spectrum has been measured by Nicovich and Wine<sup>11</sup> and Knight et al.<sup>7</sup> The results of Nicovich and Wine and Knight et al. are in excellent agreement. Nicovich and Wine<sup>11</sup> parameterized the temperature dependence for wavelengths >260 nm as the sum of two temperature dependent components,  $\sigma_0$  and  $\sigma_1$ , using the expression given in Table 4B-6. In this parameterization,  $\sigma_0$  represents absorption from the ground vibrational state and  $\sigma_1$  represents absorption from the O-O stretch vibrational level. The expression given in Table 4B-6 is recommended and the 298 K cross section values obtained from this parameterization for wavelengths >260 nm are given in Table 4B-5.

**Table 4B-5. Recommended Absorption Cross Sections of H<sub>2</sub>O<sub>2</sub> Vapor at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

Note:

<260 nm: mean of the data from Lin et al.,<sup>8</sup> Molina and Molina,<sup>9</sup> Nicovich and Wine,<sup>11</sup> and Vaghjiani and Ravishankara<sup>18</sup>260–350 nm: Nicovich and Wine,<sup>11</sup> parameterization**Table 4B-6. Mathematical Expression for Absorption Cross Sections of H<sub>2</sub>O<sub>2</sub> as a Function of Temperature**

$$10^{21} \sigma(\lambda, T) = \chi \sum_{n=0}^7 A_n \lambda^n + (1 - \chi) \sum_{n=0}^4 B_n \lambda^n$$

where T: temperature K; λ: nm; χ = (1 + exp (-1265/T))<sup>-1</sup>

$$A_0 = 6.4761 \times 10^4 \quad B_0 = 6.8123 \times 10^3$$

$$A_1 = -9.2170972 \times 10^2 \quad B_1 = -5.1351 \times 10^1$$

$$A_2 = 4.535649 \quad B_2 = 1.1522 \times 10^{-1}$$

$$A_3 = -4.4589016 \times 10^{-3} \quad B_3 = -3.0493 \times 10^{-5}$$

$$A_4 = -4.035101 \times 10^{-5} \quad B_4 = -1.0924 \times 10^{-7}$$

$$A_5 = 1.6878206 \times 10^{-7}$$

$$A_6 = -2.652014 \times 10^{-10}$$

$$A_7 = 1.5534675 \times 10^{-13}$$

Range 260–350 nm; 200–400 K

*Photolysis Quantum Yields and Product Studies.* The photodissociation quantum yield is thought to be unity. At and above 248 nm, the major photodissociation process is that leading to OH, i.e., the quantum yield for OH production is 2 (Vaghjiani and Ravishankara,<sup>19</sup> Vaghjiani et al.,<sup>20</sup> Riffault et al.<sup>12</sup>). At 248 nm Vaghjiani and Ravishankara<sup>19</sup> reported  $\Phi(\text{OH}) = 2.09 \pm 0.36$ ,  $\Phi(\text{O}) < 0.002$ , and  $\Phi(\text{H}) < 0.0002$ . Schiffman et al.<sup>13</sup> reported a slightly lower value for  $\Phi(\text{OH})$  at 248 nm of  $1.58 \pm 0.23$ ; at 193 nm they obtained  $\Phi(\text{OH}) = 1.22 \pm 0.13$ . At 222 nm Vaghjiani et al.<sup>20</sup> measured  $\Phi(\text{OH}) = 2.02 \pm 0.35$ ,  $\Phi(\text{O}) < 0.002$ , and  $\Phi(\text{H}) = 0.024 \pm 0.012$ . At 193 nm they obtained  $\Phi(\text{OH}) = 1.51 \pm 0.18$ ,  $\Phi(\text{O}) < 0.02$ , and  $\Phi(\text{H}) = 0.16 \pm 0.04$ . Riffault et al.<sup>12</sup> reported  $\Phi(\text{OH})$  values of  $1.93 \pm 0.39$  at 308 nm and  $1.96 \pm 0.50$  at 320 nm. In addition, Gerlach-Meyer et al.<sup>3</sup> reported  $\Phi(\text{H}) = 0.12 \pm 0.01$  and Schiffman et al.<sup>13</sup> reported  $\Phi(\text{OH}) = 1.22 \pm 0.13$  for 193 nm photolysis in reasonable agreement with Vaghjiani et al.<sup>20</sup> An OH quantum yield of 2 for  $\lambda > 230$  nm is recommended. For 193 nm  $\Phi(\text{OH}) = 1.7$  and  $\Phi(\text{H}) = 0.15$  are recommended.

## SECTION 4C. NO<sub>x</sub> PHOTOCHEMISTRY

### C1. NO<sub>2</sub> (nitrogen dioxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of nitrogen dioxide, NO<sub>2</sub>, in the 200–800 nm region can be separated into two principal systems: the D-X band below 250 nm and the broad B-X and A-X bands between 300 and 800 nm with a maximum around 400 nm. The forbidden C-X transition also contributes to the visible spectrum. There is enormous spectral fine structure superimposed on the broad visible system. Due to the complexity of the electronic states of NO<sub>2</sub>, it is not presently possible to predict its spectrum from molecular quantum theory within the accuracy of the experimental measurements. The absorption spectrum and cross sections of NO<sub>2</sub> have been extensively studied during the last century as summarized in Table 4C-1.

**Table 4C-1. Summary of NO<sub>2</sub> Absorption Cross Section Studies**

Study	Year	λ Range (nm)	Type*	Resolution (nm)	Temperature (K)
Holmes and Daniels <sup>21</sup>	1934	265–436	B	1	298

\* The studies summarized in Table 4C-1 are organized into three measurement categories: *Type A, absolute* cross section measurements over a broad spectral region (typically covering a few hundred nm); *Type B, absolute* cross section measurements at specific wavelengths or over narrow spectral ranges; and *Type C, relative* NO<sub>2</sub> absorption spectrum measurements over broad spectral region (typically a few hundred nm) that have been scaled to absolute cross section values using results from other studies.

In the earlier studies, the NO<sub>2</sub> ultraviolet-visible absorption cross section measurements were limited to lower spectral resolution. Since 1992, however, several sets of high resolution measurements, including temperature and pressure dependence studies, have been reported by several groups, which mainly aimed at improving the accuracy of atmospheric measurements, in particular, for the atmospheric remote sensing of NO<sub>2</sub>. However, a number of laboratory measurements were also obtained at spectral resolutions that are limited by instrumental techniques.

The JPL-97-04<sup>10</sup> recommendation for the absorption cross sections of NO<sub>2</sub> was based on the work of Bass et al.,<sup>2</sup> Schneider et al.,<sup>39</sup> and Davidson et al.<sup>9</sup> Although at room temperature the agreement between these three sets of measurements is good (within 5% between 305 and 345 nm and within 10% at the longer wavelengths), serious non-uniform wavelength calibration errors are apparent in the wavelength range 400–500 nm as described by Schneider et al.<sup>39</sup> At shorter wavelengths and for temperatures below 298 K the agreement among these three sets of data is poor. A possible cause for the discrepancies is the presence of N<sub>2</sub>O<sub>4</sub>, which is the weakly bound NO<sub>2</sub> dimer present in equilibrium with the monomer. The ratio of the abundance of the two species is concentration and temperature dependent. Corrections were needed to account for the presence of N<sub>2</sub>O<sub>4</sub> at wavelengths below 400 nm and especially near 200 nm where N<sub>2</sub>O<sub>4</sub> absorbs strongly.

Kirmse et al.<sup>26</sup> analyzed the spectra reported between 1976 and 1995 and concatenated selected (and corrected) cross sections to create a “new standard” spectrum in the range 300–708 nm at a resolution of 0.05 nm, and another spectrum extending to 908 nm at a lower resolution of 1 nm. This high resolution “new standard” spectrum consisted of the Mérienne et al.<sup>30</sup> cross sections from 300 to 500 nm, the Corcoran et al.<sup>7</sup> cross sections from 500 to 600 nm, and the Schneider et al.<sup>39</sup> cross sections from 600 to 710 nm. A critical review and evaluation of the cross section studies was performed by Orphal<sup>34</sup> and Orphal,<sup>37</sup> covering most studies published since 1995. In his evaluations Orphal<sup>34,37</sup> considered baseline problems, wavelength calibration and integrated cross sections (after convolution of high resolution cross sections of 0.1 nm or better). In addition, Vandaele et al.<sup>42</sup> derived temperature and pressure dependent parameters from high resolution spectral data obtained since 1995.

At room temperature ( $295 \pm 3$  K) there is agreement to better than 2–3% among the absolute cross sections over the wavelength range covered by the measurements of Mérienne et al.,<sup>30</sup> Coquart et al.,<sup>6</sup> Vandaele et al.,<sup>43</sup> Jenouvrier et al.,<sup>22</sup> Yoshino et al.,<sup>47</sup> Mérienne et al.,<sup>29</sup> Vandaele et al.,<sup>44</sup> Bogumil et al.,<sup>3</sup> and Nizkorodov et al.<sup>33</sup> Many of these studies differ in spectral resolution, an issue relevant to atmospheric remote sensing applications. The cross sections of Harwood and Jones<sup>19</sup> are 6–8% below most of the other studies, while the data of Harder et al.<sup>17</sup> are systematically 2–5% higher than the data of Vandaele et al.<sup>44</sup> (1998) and show a systematic baseline drift of up to 10% at the lowest temperature.

The high pressure cross section data of Vandaele et al.<sup>41</sup> (2002) and Vandaele et al.<sup>42</sup> (2003) are nearly 4% smaller than the Vandaele et al.<sup>43</sup> (1996) and Vandaele et al.<sup>44</sup> (1998) data. The cross sections of Burrows et al.<sup>4</sup> are about 6–8% lower than most recent high resolution studies (Mérienne-95, Mérienne-97, Harder, Vandaele-96, Vandaele-98). The data of Voigt et al.<sup>45</sup> show several artificial peaks (probably Xenon lamp stray light) of a few percent and baseline shifts up to 10% (partly due to residual N<sub>2</sub>O<sub>4</sub> absorption) at lower temperatures. The spectra of Bogumil et al.<sup>3</sup> were scaled to absolute values using the integrated cross section of Vandaele et al.<sup>44</sup> (1998).

The temperature effect on the NO<sub>2</sub> absorption cross sections has been studied by only a few research teams, as given in Table 4C-1. The variation of the absorption consists mainly in an increase of the differential absorption cross sections with decreasing temperature. In his analysis of the temperature dependence of the cross sections in the 300–700 nm region, Orphal<sup>35</sup> (2003) observed a tilt in the baseline with decreasing temperature in the data of Davidson et al.,<sup>9</sup> Burrows et al.,<sup>4</sup> and Bogumil et al.<sup>3</sup> but less pronounced in the data of Harwood and Jones,<sup>19</sup> Harder et al.,<sup>17</sup> and Vandaele et al.<sup>41</sup> (2002). This is due to a change in the thermal population of the lower vibrational and rotational states causing large discrepancies in the relative change and the absolute magnitude of the absorption cross sections. The comparison of the high resolution absolute cross sections at temperatures below ambient reveals significant discrepancies in absolute magnitude of cross sections due to spectral resolution, baseline differences and possible wavelength calibration. For the temperatures 242 ± 2 and 220 ± 3 K, the overall agreement is within 15% in the region 350–500 nm, however outside this range the discrepancies are much larger. The integrated cross sections for the range 400–500 nm were calculated by Orphal<sup>35</sup> (2003) to be  $(4.50 \pm 0.10) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1} \text{ nm}$  and are independent of temperature, as recently shown by Nizkorodov et al.<sup>33</sup> for the temperature range 215–298 K.

Orphal<sup>35</sup> (2003) and Vandaele et al.<sup>42</sup> (2003) compared the spectra after degrading the high resolution spectra to a lower resolution. At 220 K the best agreement (within 1.6%) is obtained between the data of Coquart et al.,<sup>6</sup> Mérienne et al.<sup>29</sup> (1997), and Vandaele et al.<sup>44</sup> (1998). The data of Harder et al.<sup>17</sup> differ by 3.7% from the Vandaele et al.<sup>44</sup> (1998) data below 500 nm but seem to contain more noise at longer wavelengths. The data of Voigt et al.<sup>45</sup> show larger disagreement, which is different in every temperature data set. At 223 K their data are 22% lower than the Vandaele et al.<sup>44</sup> (1998) values.

The temperature dependence of the NO<sub>2</sub> cross sections in the entire ultraviolet and visible regions can be reproduced within the experimental uncertainties using analytical expressions, at least at low and moderate spectral resolutions (i.e., 0.05 nm and less). Linear functions were proposed by Davidson et al.,<sup>9</sup> Kirmse et al.,<sup>26</sup> and Vandaele et al.<sup>41</sup> (2002), a quadratic polynomial by Burrows et al.,<sup>4</sup> and a double exponential function by Voigt et al.<sup>45</sup> For the high resolution spectra Nizkorodov et al.<sup>33</sup> concluded that a linear temperature dependence is not valid and a successful parameterization requires further work.

The NO<sub>2</sub> cross sections vary as a function of total pressure but these effects are only observed at high spectral resolution, i.e., better than 0.01 nm, as investigated by Harder et al.,<sup>17</sup> Wennberg et al.,<sup>46</sup> Vandaele et al.<sup>44</sup> (1998), Voigt et al.,<sup>45</sup> Vandaele et al.<sup>41</sup> (2002), and Nizkorodov et al.<sup>33</sup> using NO<sub>2</sub>/N<sub>2</sub> (or air) mixtures at total pressures up to 1 atm. Nizkorodov et al.<sup>33</sup> showed that a simple Lorentzian broadening model with linear dependence of the Lorentz width on pressure provides an adequate description of the pressure broadening effects in NO<sub>2</sub>.

The current recommendation is based on the data of Vandaele et al.<sup>44</sup> (1998). Table 4C-2 lists recommended cross sections for 294 and 220 K averaged over atmospherically relevant intervals.

*Photolysis Quantum Yield and Product Studies:* A number of NO<sub>2</sub> photolysis quantum yield studies in the atmospherically important 300–470 nm region have been reported: Jones and Bayes<sup>24</sup> for the wavelength range 295–445 nm and at 492 nm, 546 nm and 579 nm; Gaedtke and Troe<sup>13</sup> in the range 313–416 nm; Harker et al.<sup>18</sup> for the range 375–420 nm at 1 nm intervals; Davenport<sup>8</sup> for the range 390–420 nm at 223 and 300 K; Gardner et al.<sup>14</sup> for the range 334–404 nm at 298 K, and at 404 nm at 273 and 370 K; and Roehl et al.<sup>38</sup> in the range 388–411 nm at 248 and 298 K. In the range 360–398 nm the  $\Phi_1$  values show a wide scatter, with differences of as much as 60%, especially for the data of Harker et al.<sup>18</sup> Although Gardner et al.<sup>14</sup> obtained values of  $\Phi_1$  between  $0.89 \pm 0.05$  and  $0.97 \pm 0.06$  in the range 379–397 nm, they made a critical assessment of the quantum yield data and recommended that  $\Phi_1$  is near unity at wavelengths up to and slightly beyond the dissociation limit of  $\lambda_0 = 397.95$  nm (Jost et al.<sup>25</sup>) and then rapidly decreases to near zero at 424 nm. However, Roehl et al.<sup>38</sup> determined  $\Phi_1 = (0.93 \pm 0.10)$  in the range 388–398 nm at 298 K, and  $\Phi_1 = (0.90 \pm 0.10)$  at 248 K. Troe<sup>40</sup> conducted a critical reanalysis of the quantum yield data of Gardner et al.<sup>14</sup> and Roehl et al.<sup>38</sup> below  $\lambda_0$  and concluded that certain secondary reactions were not correctly accounted for, and recommended corrections for both data sets. The recommended quantum yield values in Table 4C-3 are based on the data of Roehl et al.<sup>38</sup> as corrected by Troe.<sup>40</sup>

## C2. NO<sub>3</sub> (nitrate radical)

[Back to Index](#)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

*Absorption Cross Sections:* The visible absorption spectrum of the NO<sub>3</sub> radical contains ~20 diffuse bands between 400 and 700 nm, Figure 4C-1. The most intense features are the bands for the 0-0 and 1-0 transitions in the symmetric N-O stretching vibration in the excited state that are centered at 662 and 623 nm, respectively. The absorption cross section of the 0-0 band at 662 nm is of special interest, since it is commonly used to monitor NO<sub>3</sub> both in the laboratory and in the atmosphere.

The absorption cross sections of NO<sub>3</sub> have been the subject of many laboratory studies. The spectroscopy of NO<sub>3</sub> has been reviewed by Wayne et al.<sup>21</sup> Although there is good agreement for the positions of the absorption features, the range in reported absolute cross sections is nearly a factor of two. The studies and reported cross sections values at the 662 nm peak are summarized in Table 4C-4.

**Table 4C-4. Summary of NO<sub>3</sub> Absorption Cross Section Studies**

	Study	Year	NO <sub>3</sub> source Technique	T (K)	$\lambda$ (nm)	Resolution (nm)	$\sigma(662 \text{ nm}) (10^{-17} \text{ cm}^2)$

<sup>a</sup> Estimate for 300 K by Wayne et al.<sup>21</sup> from the data of Schott and Davidson.<sup>19</sup>

<sup>b</sup> Improvement by Graham and Johnston<sup>6</sup> using their more actual kinetic data.

<sup>c</sup> The overall uncertainty ( $\pm 15\%$ ) includes the uncertainty of the absorbance measurement ( $\pm 5\%$ ) and the uncertainty of  $\sigma(\text{ClONO}_2)$  ( $\pm 10\%$ ). The value for  $\sigma(662 \text{ nm})$  obtained by the flash photolysis method is preferred by Sander<sup>17</sup> over that obtained by the discharge flow method.

<sup>d</sup> Recommendation by Wayne et al.<sup>21</sup>

The JPL02-25<sup>18</sup> evaluation recommended a cross section value of  $(2.00 \pm 0.25) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 662 nm derived from an average of the results from studies 5, 6, and 8–12 given in Table 4C-4. The recommendation by Wayne et al.<sup>21</sup> averaged the data of the more recent studies, studies 9–12, and resulted in

a slightly higher value of  $(2.10 \pm 0.20) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ . Higher values for the absorption cross section at 662 nm were obtained in the more recent studies by Yokelson et al.<sup>22</sup> and Orphal et al.<sup>13</sup> Here, the results from Sander<sup>17</sup> and Yokelson et al.<sup>22</sup> are averaged to derive a recommended cross section of  $(2.25 \pm 0.15) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 662 nm. The recommended absorption cross sections at other wavelengths in Table 4C-5 are taken from Sander<sup>17</sup> after normalization to this value, which is actually only a reduction of 1.3% from the originally reported data.

The studies of the absorption spectrum temperature dependence indicate an increase of the 662 nm peak absorption cross section with decreasing temperature. Ravishankara and Mauldin<sup>15</sup> reported an increase of 42% between 298 and 220 K. Sander<sup>17</sup> reported an increase of 17% between 298 and 230 K. Yokelson et al.<sup>22</sup> reported increases of 34% between 298 and 200 K and 24% between 298 and 230 K. Osthoff et al.<sup>14</sup> reported a decrease of 48% between 298 and 388 K. Cantrell et al.<sup>3</sup> reported a temperature independent cross section over the temperature range 210–348 K of  $2.06 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  that is in disagreement with the findings from the other studies. Osthoff et al.<sup>14</sup> combined their data with the data from Yokelson et al.<sup>22</sup> and modified the parameterization given by Yokelson et al.<sup>22</sup> for the peak cross section temperature dependence slightly as:

$$\sigma(662 \text{ nm}, T) = (4.582 \pm 0.096) - [(0.00796 \pm 0.0031) \times T] \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$$

for the range 220–388 K. Orphal et al.<sup>13</sup> interpreted the temperature dependence as resulting from changes in the ground vibrational state population of  $\text{NO}_3$  ( $D_{3h}$  symmetry) and derived a formula for the cross section ratio as function of temperature

$$\sigma(T)/\sigma(298 \text{ K}) = [1 - \exp(-1096.4/T) - 2 \exp(-529.5/T)] / [1 - \exp(-1096.4/298.0) - 2 \exp(-529.5/298.0)]$$

where the values of 1096.4 K and 529.5 K are the vibrational energies of  $762 \text{ cm}^{-1}$  and  $368 \text{ cm}^{-1}$  divided by the Boltzmann constant. There is excellent agreement between the calculated temperature dependence using the Orphal model and the empirical relationships from Yokelson et al.<sup>22</sup> and Osthoff et al.<sup>14</sup>

*Photolysis Quantum Yield and Product Studies:* The quantum yields  $\Phi_1$  and  $\Phi_2$  have been measured by Graham and Johnston,<sup>6</sup> and at higher spectral resolution by Magnotta and Johnston,<sup>9</sup> who report the product of the cross section times the quantum yield in the 400 to 630 nm range. The total quantum yield value,  $\Phi_1 + \Phi_2$ , computed from the results of Magnotta and Johnston<sup>9</sup> and the cross sections of Graham and Johnston,<sup>6</sup> is about 1.5 for  $\lambda < 585 \text{ nm}$ , based on the nearly constant yield of the major product  $\text{O}({}^3\text{P})$ , and a quantum yield for the NO production  $\Phi_1$  near zero. Because systematic errors seem to exist in these data, in their review Wayne et al.<sup>21</sup> normalized  $\Phi_2$  quantum yields to unity at  $\lambda < 585 \text{ nm}$ . The quantum yield for the NO production,  $\Phi_1$ , increases from zero at 585 nm to a maximum of  $\Phi_1 = 0.35$  at 595 nm, where  $\Phi_2 = 0.65$ . At longer wavelengths both  $\Phi_1$  and  $\Phi_2$  decrease to a value of zero at  $\lambda = 640 \text{ nm}$ . Orlando et al.<sup>12</sup> measured the  $\text{O}({}^3\text{P})$  and NO quantum yields in the photolysis of  $\text{NO}_3$  between 570 and 635 nm. They qualitatively confirm the earlier measurements by Johnston and coworkers but provide more accurate data for both channels. The  $\text{O}({}^3\text{P})$  quantum yield was found to be unity in the wavelength range 570–585 and to decrease to 0.1 at 635 nm. They observed anomalously low  $\text{O}({}^3\text{P})$  yields in the region of the strong absorption band near 623 nm. The quantum yields for NO formation were <0.10 at 580 nm and  $0.20 \pm 0.10$  near 590 nm. The wavelength dependence of  $\Phi_1$  and  $\Phi_2$  are similar to those recommended in the review of Wayne et al.<sup>21</sup>

In a molecular beam study, Davis et al.<sup>5</sup> investigated the photodissociation processes of  $\text{NO}_3$  over the wavelength range 532–662 nm and determined a sharp threshold for the dissociation of internally cold  $\text{NO}_3$  into  $\text{NO}_2$  and  $\text{O}({}^3\text{P})$  at 587 nm. At shorter wavelengths, e.g. 585 nm, the  $\text{NO} + \text{O}_2$  yield dropped to <0.05. At excitation energies just below this threshold, i.e.,  $\lambda = 588 \text{ nm}$ , a large quantum yield ( $0.70 \pm 0.10$ ) for a concerted three-center rearrangement was observed, resulting in  $\text{NO} + \text{O}_2({}^3\Sigma_g^-, {}^1\Delta)$ . The yield of this  $\text{NO} + \text{O}_2$  process decreases at longer wavelengths to zero at 613 nm. At  $\lambda > 588 \text{ nm}$  the  $\text{O} + \text{NO}_2$  channel yield arises from vibrational excitation of the ground electronic state of  $\text{NO}_3$ . These results imply that for thermally equilibrated  $\text{NO}_3$  the branching ratios for dissociation of both channels (1) and (2) will strongly depend on temperature, especially near the threshold wavelength.

Johnston et al.<sup>7</sup> re-analyzed the available laboratory data relevant to  $\text{NO}_3$  photolysis, including quantum yield data for NO and  $\text{NO}_2$  formation, fluorescence, and threshold energies reported in the molecular beam study. Their model reproduces the wavelength dependent quantum yield values for  $\Phi(\text{O} + \text{NO}_2)$ ,  $\Phi(\text{NO} + \text{O}_2)$  and  $\Phi(\text{fluorescence})$  at 190, 230, and 298 K. At 298 K the calculated  $\Phi(\text{O} + \text{NO}_2)$  quantum yields agree reasonably well with those obtained by Orlando et al.,<sup>12</sup> but shows a systematic offset in the wavelength range 605–620 nm. The calculated  $\Phi(\text{NO} + \text{O}_2)$  product yield agrees with those reported by Magnotta and Johnston<sup>9</sup> within the scatter of the experimental data.

The recommended quantum yields in Table 4C-6 over the wavelength range 685–640 nm at 190, 230, and 298 K are taken from Johnston et al.<sup>7</sup> For  $\lambda < 585$  nm,  $\Phi(O + NO_2) = 1$ , and  $\Phi(NO + O_2) = 0$  and for  $\lambda > 640$  nm  $\Phi(O + NO_2)$  and  $\Phi(NO + O_2)$  are zero. Photodissociation rates have been calculated by Johnston et al.<sup>7</sup> for overhead sun in the stratosphere to be

$$J(NO + O_2) = 0.0201 \text{ s}^{-1}$$

$$J(NO_2 + O) = 0.156 \text{ s}^{-1}$$

→ N <sub>2</sub> + O( <sup>1</sup> S)	571 kJ mol <sup>-1</sup>	210 nm	(4)

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of nitrous oxide, N<sub>2</sub>O, has been measured in numerous studies covering the wavelength range 108–315 nm at temperatures between 194 and 302 K. A summary of the available spectroscopic studies is given in Table 4C-7.

**Table 4C-7. Summary of N<sub>2</sub>O Cross Section Studies**

Study	Year	Temperature (K)	Wavelength range (nm)	Resolution (nm)
Romand and Mayence <sup>21</sup>	1949	291	139–231	—

Rontu Carlon et al. <sup>22</sup>	2010	210–350	184.95, 202.206, 206.200, 213.857, 228.8	atomic lines
SPARC Evaluation <sup>13</sup>	2013	—	—	—

The N<sub>2</sub>O spectrum has a broad absorption band between 160 and 260 nm with the peak near 182 nm ( $\sigma_{\max} = (1.24\text{--}1.47) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ ) and a stronger but weaker band between 137 and 160 nm with the maximum near 145 nm ( $\sigma_{\max} = (5\text{--}6) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ ). There is good agreement between the results from Selwyn et al.<sup>23</sup> and Hubrich and Stuhl.<sup>10</sup> The agreement over the entire 160–260 nm band is better than 15% and the difference at 182 nm is 5% with the data of Selwyn et al.<sup>23</sup> being greater. The results of Mérienne et al.<sup>14</sup> and Rontu Carlon et al.<sup>22</sup> are in excellent agreement, better than 5% and 3%, respectively, with those of Selwyn et al.<sup>23</sup> The results of Cantrell et al.<sup>3</sup> and Creasey et al.<sup>5</sup> at 184.9 nm are also in good agreement with the results of Selwyn et al.<sup>23</sup> The high resolution absorption spectrum reported by Yoshino et al.<sup>29</sup> shows the diffuse vibrational structure around the maximum and their absolute cross sections are close to those reported by Hubrich and Stuhl.<sup>10</sup> At wavelengths >250 nm, there are large discrepancies between the results from Bates and Hayes<sup>1</sup> and Johnston and Selwyn.<sup>12</sup> The recommended cross sections listed in Table 4C-8 are based on the room temperature results at 160, 165, and 170 nm of Hubrich and Stuhl<sup>10</sup> and the room temperature data between 173–240 nm from Selwyn et al.<sup>23</sup>

The VUV absorption spectrum of N<sub>2</sub>O has been measured by Hitchcock et al.<sup>9</sup> (16.8–155 nm) and Chan et al.<sup>4</sup> (6.1–168 nm). The absorption cross section at 123.6 nm was measured by Bertrand et al.<sup>2</sup> The cross section results from Chan et al. and Hitchcock et al. agree to within 6% at 124 nm, while the value reported by Bertrand et al. is less by nearly a factor of 3. The reason for the difference is unknown. The recommended Lyman- $\alpha$  cross section is adopted from SPARC,<sup>13</sup> which used a linear interpolation of the Chan et al. cross section data at 118 and 124 nm to obtain a Lyman- $\alpha$  cross section of  $2.4 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  with an uncertainty factor of 1.5 (2 $\sigma$ ).

The temperature dependence of the N<sub>2</sub>O absorption cross section in the atmospherically relevant wavelength region has been measured by Selwyn et al.,<sup>23</sup> Hubrich and Stuhl,<sup>10</sup> Mérienne et al.,<sup>14</sup> and Rontu Carlon et al.<sup>22</sup> These studies report a decrease in absorption cross section with decreasing temperature. The Hubrich and Stuhl data has considerable scatter in the spectrum wavelength dependence and is not considered in the recommendation. The Rontu Carlon et al. study is in excellent agreement, to within 3%, with the JPL10-6 recommendation at 202.206, 206.200, and 213.857 nm. There is a systematic difference in the cross section temperature dependence at 228.8 nm between the Mérienne et al. and Rontu Carlon et al. data and that of JPL10-6, where the difference is ~18% at 210 K. The empirical cross section parameterization given by Selwyn et al.<sup>23</sup> given in Table 4C-9 is recommended.

On the basis of the Selwyn et al., Mérienne et al., and Rontu Carlon et al. studies, an uncertainty factor of 1.08 (2 $\sigma$ ) is recommended for the 298 K absorption cross sections over the wavelength range 185–220 nm.

The uncertainty factor at lower temperatures is estimated to be slightly greater with a value of 1.12 ( $2\sigma$ ) at 200 K.

Isotopomer specific cross sections for  $^{14}\text{N}^{14}\text{NO}$ ,  $^{15}\text{N}^{14}\text{NO}$ ,  $^{14}\text{N}^{15}\text{NO}$ ,  $^{15}\text{N}^{15}\text{NO}$  over the wavelength range 181–218 nm have been reported by von Hessberg et al.<sup>28</sup> at 233 and 283 K. They observed a slight decrease in the absorption cross sections of  $^{14}\text{N}^{15}\text{NO}$  and  $^{15}\text{N}^{15}\text{NO}$  compared to those of  $^{14}\text{N}^{14}\text{NO}$  and  $^{15}\text{N}^{14}\text{NO}$ . They also observed a systematic decrease in absorption cross section with decreasing temperature.

**Photolysis Quantum Yield and Product Studies:** The quantum yield for photodissociation is unity in the range 140–230 nm and the photoproducts are almost exclusively N<sub>2</sub> and O(<sup>1</sup>D) (Zelikoff and Aschenbrand,<sup>31</sup> Greiner,<sup>7</sup> Paraskevopoulos and Cvetanovic,<sup>16</sup> Preston and Barr,<sup>17</sup> and Simonaitis et al.<sup>25</sup>). The yield of N(<sup>4</sup>S) and NO(<sup>2</sup>Π) is less than 1% (Greenblatt and Ravishankara<sup>6</sup>). Nishida et al.<sup>15</sup> reported the yield of O(<sup>3</sup>P) at 193 nm to be  $0.005 \pm 0.002$ .

Several groups have investigated the isotopic fractionation of N<sub>2</sub>O resulting from photolysis in the UV. Fractionation factors have been measured following photolysis at select wavelengths in the 193–213 nm range by Turatti et al.<sup>27</sup> (using high resolution FTIR spectroscopy), Röckmann et al.<sup>19</sup> (using a modified isotope ratio mass spectrometric technique), Rahn et al.<sup>18</sup> (utilizing isotope ratio mass spectrometry), and Zhang et al.<sup>33</sup> (using low resolution FTIR spectroscopy). Röckmann et al.<sup>20</sup> utilized a broadband photolysis source centered around 200 nm that simulated stratospheric actinic fluxes. The results are in reasonably good agreement and indicate that the fractionation factors increase with increasing wavelength between 193 and 213 nm. Furthermore, the fractionation factors show a clear dependence on the position of the <sup>15</sup>N atom, in agreement with the theoretical zero point energy model of Yung and Miller.<sup>30</sup> However, the Yung and Miller calculations underestimate the laboratory results by about a factor of two. A more detailed Hermite propagation model used by Johnson et al.<sup>11</sup> achieved better agreement with experimental enrichment factors. Analysis of the isotopic composition of stratospheric air samples yields results that are in qualitative agreement with the laboratory results, confirming that photolysis is the predominant sink for N<sub>2</sub>O.<sup>8,20</sup> On the other hand, the fractionation factors measured in the atmospheric samples are smaller than those reported from the laboratory studies, indicating the influence of atmospheric diffusion and mixing (Röckmann et al.<sup>20</sup>).

#### C4. $\text{N}_2\text{O}_4$ (dinitrogen tetraoxide)

[Back to Index](#)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

**Absorption Cross Sections:** The UV/vis absorption spectrum of dinitrogen tetraoxide,  $\text{N}_2\text{O}_4$ , has been derived from absorption measurements of  $\text{NO}_2$ - $\text{N}_2\text{O}_4$  mixtures. The available studies are summarized in Table 4C-10. The  $\text{N}_2\text{O}_4$  absorption spectrum consists of a band between 300 and 400 nm with a maximum at  $\sim 340$  nm, a second less pronounced maximum near  $\sim 265$  nm, and a strong absorption at shorter wavelengths with a maximum near 190 nm. For the wavelength region 185–360 nm, there is good agreement for the shape of the absorption spectrum but there are discrepancies in the absolute absorption cross sections. In the region below 240 nm, there is good agreement between the absorption cross sections of Bass et al.<sup>1</sup> and Schneider et al.<sup>8</sup> whereas the values reported by Mérienne et al.<sup>6</sup> are lower by  $\sim 30\%$ . In the region between 250 and 300 nm, the results of Vandaele et al.<sup>9</sup> are systematically lower than the results of Mérienne et al.<sup>6</sup> by  $\sim 15\%$  whereas the results of Bass et al.<sup>1</sup> are higher by  $\sim 30\%$ . In the region 300–380 nm, Harwood and Jones<sup>3</sup> reported a systematic study of the temperature dependence of the  $\text{N}_2\text{O}_4$  absorption spectrum. The absorption cross sections near the peak at 340 nm show a weak dependence on temperature over the range 213–253 K. There is good agreement between the results of Hall and Blacet,<sup>2</sup> the low-temperature data of Harwood and Jones,<sup>3</sup> and the results of Vandaele et al.<sup>9</sup> with the absorption cross sections at 340 nm agreeing to within 5%. Bass et al.<sup>1</sup> and Mérienne et al.<sup>6</sup> report cross section values at 340 nm that are 25% and 15% higher, respectively. The recommended cross section values in Table 4C-11 are averages over 2 nm intervals of the high resolution (0.01–0.03 nm) spectrum reported by Vandaele et al.<sup>9</sup> between 252 and 390 nm at 220 K.

**Photolysis Quantum Yield and Product Studies:** No recommendation.

## C5. N<sub>2</sub>O<sub>5</sub> (dinitrogen pentoxide)

[Back to Index](#)

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

*Absorption Cross Sections:* The UV/vis absorption spectrum of dinitrogen pentoxide, N<sub>2</sub>O<sub>5</sub>, exhibits an absorption maximum at 160 nm with continuously decreasing absorption cross sections toward longer wavelengths. The absorption cross sections of N<sub>2</sub>O<sub>5</sub> have been measured in a number of studies that are summarized in Table 4C-12. The room temperature values from Yao et al.<sup>14</sup> and Harwood et al.<sup>3–5</sup> agree to within 10–20% at wavelengths above 250 nm. Below 250 nm, the cross sections reported by Yao et al.<sup>14</sup> that were recommended in the JPL-1997 evaluation are systematically higher than those reported by Harwood et al.<sup>3</sup> by up to a factor of ~2 at 208 nm. A possible explanation for this discrepancy was proposed by Harwood et al.<sup>3</sup> as due to contributions to the measured absorption by HNO<sub>3</sub> impurities. Harwood et al.<sup>3</sup> used N<sub>2</sub>O<sub>5</sub> samples containing less than a 1% HNO<sub>3</sub> impurity. This explanation was later confirmed by the measurements of Osborne et al.<sup>11</sup> who also used thoroughly purified N<sub>2</sub>O<sub>5</sub> samples and reported absorption cross sections in agreement with those of Harwood et al.<sup>3</sup> at 210–240 nm but at a lower temperature.

The recommended absorption cross sections listed in Table 4C-13 are the mean of the data from Yao et al.<sup>14</sup> and Osborne<sup>11</sup> for 200–208 nm, the mean of the data from Yao et al.,<sup>14</sup> Osborne et al.,<sup>11</sup> and Harwood et al.<sup>3</sup> for 210–240 nm, the data of Harwood et al.<sup>3</sup> for 242–398 nm, and the data of Harwood et al.<sup>4</sup> for 400–420 nm.

The temperature dependence of the absorption spectrum was measured by Harwood et al.<sup>3</sup> and Yao et al.<sup>14</sup> and found to be significant for wavelengths >280 nm. The absorption cross sections decrease with decreasing temperature and the magnitude of the effect increases with increasing wavelength. Harwood et al.<sup>4</sup> parameterized the temperature dependence using the relationship

$$\log_{10}(\sigma) = A(\lambda) + 1000 \times B(\lambda)/T$$

which is valid over the temperature range 233–295 K. The A and B coefficients are given in Table 4C-13.

**Table 4C-12. Summary of N<sub>2</sub>O<sub>5</sub> Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength (nm)

*Photolysis Quantum Yield and Product Studies:* There are several studies of N<sub>2</sub>O<sub>5</sub> primary photolysis products for wavelengths between 248 and 352.5 nm as summarized in Table 4C-14. The NO<sub>3</sub> radical is produced with unity quantum yield at wavelengths >300 nm. At shorter wavelengths the NO<sub>3</sub> quantum yield decreases to a value of ~0.71 at 248 nm and the O(<sup>3</sup>P) atom quantum increases. The study of Oh et al.<sup>10</sup> indicates that the primary photolysis products other than NO<sub>3</sub> are a wavelength dependent mixture of NO<sub>2</sub>, NO<sub>2</sub>\* and NO + O, where NO<sub>2</sub>\* represents electronically excited NO<sub>2</sub> that is most likely the <sup>2</sup>B<sub>1</sub> state. For atmospheric model calculations unit photolysis quantum yields of NO<sub>3</sub> and NO<sub>2</sub> are recommended for wavelengths >300 nm.

**C6. HONO (nitrous acid)**[Back to Index](#)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of nitrous acid, HONO, consists of a highly structured absorption band between 300 and 400 nm due to vibrational progressions in the A<sup>1</sup>A'' ← X<sup>1</sup>A' transition, with a maximum intensity near 354 nm and a stronger continuous absorption band at shorter wavelengths with a maximum near 205 nm. A summary of the HONO room temperature absorption cross section studies for the near UV band is given in Table 4C-15.

**Table 4C-15. Summary of HONO Absorption Cross Section Studies**

Study	Year	Wavelength Range (nm)	Resolution (nm)	$10^{20} \sigma$ (354 nm) (cm <sup>2</sup> )
Johnston and Graham <sup>8</sup>	1974	300–399	0.87	12.3

Kenner et al. <sup>9</sup>	1986	184–274	0.38	—
Vasudev <sup>15</sup>	1990	310–393	—	(49.7)*
Bongartz et al. <sup>3</sup>	1991	300–400	0.1 ( $\lambda < 375$ nm) 0.8 ( $\lambda < 375$ nm)	64.2**
Bongartz et al. <sup>2</sup>	1994	300–400	0.1 ( $\lambda < 375$ nm) 0.8 ( $\lambda < 375$ nm)	54.9**
Febo et al. <sup>6</sup>	1996	50–380	1	49.7**
Pagsberg et al. <sup>10</sup>	1997	348–376	0.06	50.2
Brust et al. <sup>4</sup>	2000	323–394	0.5	38.9
Stutz et al. <sup>14</sup>	2000	291–404	$0.061 \pm 0.003$	52.2
Wang and Zhang <sup>16</sup>	2000	352.2 354.2 357.0	<0.1	48.9
Gratien et al. <sup>7</sup>	2009	300–400	0.18	—

Notes:

\* Normalized to the spectrum of Stockwell and Calvert<sup>13</sup>\*\* Bongartz et al.<sup>2</sup> corrected their 1991 results by a factor of 0.855

There is good agreement among the various data sets for the peak positions and discrepancies in the peak cross sections are generally a consequence of the differences in measurement spectral resolution. Stutz et al.<sup>14</sup> normalized the cross section data from earlier studies to a resolution of 1 nm, resulting in an agreement of better than 10% between their results and those of Bongartz et al.,<sup>2</sup> Pagsberg et al.,<sup>10</sup> and Vasudev.<sup>15</sup> The measurements of Stockwell and Calvert<sup>13</sup> are in reasonable agreement with the more recent studies. The cross sections from Cox and Derwent<sup>5</sup> are greater by ~26% (presumably due to uncorrected NO<sub>2</sub> absorption) and those from Johnston and Graham<sup>8</sup> are less by 70% (presumably due to non-equilibrium of the NO/NO<sub>2</sub>/H<sub>2</sub>O mixture during the measurement) than the more recent studies. The source of the discrepancy with the measurements of Brust et al.<sup>4</sup> is unknown. Gratien et al.<sup>7</sup> performed simultaneous measurements of HONO absorption spectra in the IR and UV and confirmed that the UV cross sections of Bongartz et al.<sup>2</sup> and Stutz et al.<sup>14</sup> are consistent to within 5% with independent infrared studies and that the UV cross sections of Brust et al.<sup>4</sup> are underestimated by ~22%.

The short wavelength absorption band was measured by Cox and Derwent<sup>5</sup> (200–300 nm, <0.1 nm resolution) and Kenner et al.<sup>9</sup> (184–274 nm, 0.38 nm resolution). The reported spectra are in quantitative agreement over the wavelength range 220–270 nm. The sharp peak at 215 nm reported by Cox and Derwent<sup>5</sup>, however, was not observed by Kenner et al.,<sup>9</sup> who provide a number of arguments for the correctness of their results.

The recommended absorption cross sections in Table 4C-16 are a combination of data as follows: for the wavelength region 184–274 nm data was taken from Kenner et al.<sup>9</sup> as read from a figure in their paper; for the wavelength region 296–396 nm data was taken from Stutz et al.;<sup>14</sup> for the wavelength regions 296–325 nm and 371–396 nm averages over 1 nm intervals of the Stutz et al.<sup>14</sup> high resolution spectrum are reported; and for the highly structured region 326–370 nm averages over 0.5 nm intervals were used.

**Photolysis Quantum Yield and Product Studies:** The photolysis quantum yield of HONO at wavelengths above the dissociation threshold are unity. The OH radical quantum yield at  $365 \pm 5$  nm was determined by Cox and Derwent<sup>5</sup> to be  $(0.92 \pm 0.16)$ . Wollenhaupt et al.<sup>17</sup> determined an upper limit of 0.01 for the quantum yield of H atom formation for photolysis at 351 nm. The OH(A) quantum yield from HONO laser photolysis at 193 nm was measured to be  $1.8 \times 10^{-5}$  by Kenner et al.<sup>9</sup> The H + NO<sub>2</sub> (X<sup>2</sup>A<sub>1</sub>, A<sup>2</sup>B<sub>2</sub>, B<sup>2</sup>B<sub>1</sub>, C<sup>2</sup>A<sub>2</sub>) product channels in the photodissociation of HONO at 193.3 nm were examined by Amaral et al.<sup>1</sup> and branching ratios of the NO<sub>2</sub> electronic states estimated to be X<sup>2</sup>A<sub>1</sub> : A<sup>2</sup>B<sub>2</sub> : B<sup>2</sup>B<sub>1</sub> : C<sup>2</sup>A<sub>2</sub>  $\approx 0.13 : 0.21 : 0.66$ , respectively.

	→ HONO (a <sup>3</sup> A)+ O( <sup>3</sup> P)	–	–	(6)

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

**Absorption Cross Sections:** The UV absorption spectrum of nitric acid, HNO<sub>3</sub>, consists of a strong absorption band between 150 and 240 nm with the maximum near 183 nm and a second band near 270 nm that appears as a shoulder on the long wavelength wing of the strong band. The recommended absorption cross sections and their temperature dependence for the region 192–350 nm listed in Table 4C-17 are taken from the work of Burkholder et al.<sup>3</sup> The temperature effect is very important for estimates of atmospheric photodissociation rate coefficients. The results of Burkholder et al.<sup>3</sup> agree well (to within 10% above 200 nm) with those of Rattigan et al.<sup>15,16</sup> at room temperature, whereas Rattigan et al.<sup>15,16</sup> report significantly smaller cross section values at 239 K (15–30% smaller in the range 220–330 nm and ~50% smaller at 330 nm). The recommended room temperature absorption cross sections are also in very good agreement with the data of Molina and

Molina<sup>12</sup> (<15% difference up to 310 nm) and in good agreement with the values reported by Biaume<sup>1</sup> and Johnston and Graham,<sup>8</sup> except at long wavelength. Okabe<sup>14</sup> reported cross sections in the 110–190 nm range that are 20–30% lower than those of Burkholder et al.,<sup>3</sup> Biaume,<sup>1</sup> and Johnston and Graham<sup>8</sup> in the region 185–190 nm. Suto and Lee<sup>19</sup> reported cross sections between 105 and 210 nm that are 10–20% higher than those of Burkholder et al.,<sup>3</sup> Biaume,<sup>1</sup> and Johnston and Graham<sup>8</sup> in the region 185–190 nm, but show excellent agreement with the results of Molina and Molina<sup>12</sup> above 185 nm and Burkholder et al.<sup>3</sup> above 189 nm.

On the basis of the results from the Biaume, Burkholder et al., Johnston and Graham, and Rattigan et al. studies, uncertainty factors for the  $\text{HNO}_3$  room temperature absorption cross sections in the wavelength regions 190–200 nm, 205–330 nm, and 335–350 nm are 1.1, 1.06, and 1.2 ( $2\sigma$ ), respectively. The uncertainty factors at temperatures <298 K are expected to be greater in the 335–350 nm region, but are difficult to estimate without additional studies.

**Photolysis Quantum Yield and Product Studies:** There have been a number of room temperature  $\text{HNO}_3$  photolysis studies conducted at wavelengths between 193 and 320 nm from which quantum yields have been derived. On the basis of end-product analysis, Johnston et al.<sup>7</sup> reported a quantum yield of ~1 for the  $\text{OH} + \text{NO}_2$  channel in the 200–315 nm range. Margitan and Watson<sup>11</sup> used atomic resonance fluorescence to determine the quantum yield for O atom production at 266 nm to be 0.03 and that for H atom production to be  $\leq 0.002$ . Jolly et al.<sup>9</sup> measured a quantum yield for OH production of  $0.89 \pm 0.08$  at 222 nm. Turnipseed et al.<sup>20</sup> reported OH quantum yields of  $(0.95 \pm 0.09)$  at 248,  $(0.90 \pm 0.11)$  at 222 nm, and  $0.33 \pm 0.06$  at 193 nm. Turnipseed et al.<sup>20</sup> also reported quantum yields for production of O atoms,  $\text{O}({}^3\text{P}) + \text{O}({}^1\text{D})$ , to be  $0.031 \pm 0.01$ ,  $0.20 \pm 0.03$  and  $0.81 \pm 0.13$  at 248, 222, and 193 nm, respectively. Both  $\text{O}({}^3\text{P})$  and  $\text{O}({}^1\text{D})$  atom formation was observed at 222 and 193 nm but only  $\text{O}({}^3\text{P})$  was detected at 248 nm. At 193 and 222 nm the  $\text{O}({}^1\text{D})$  yield was determined to be 40% of the total O atom yield, yielding  $\Phi(\text{O}({}^1\text{D})) = 0.28 \pm 0.07$  at 193 nm. Turnipseed et al.<sup>20</sup> reported upper limits for  $\Phi(\text{H}({}^2\text{S}))$  of  $\leq 0.002$  at 238 nm,  $\leq 0.01$  at 222 nm, and  $\leq 0.012$  at 193 nm. Riffault et al.<sup>17</sup> reported  $\Phi(\text{OH})$  values of  $0.88 \pm 0.09$  at 248 nm and  $1.05 \pm 0.29$  at 308 nm. Schiffman et al.<sup>18</sup> reported  $\Phi(\text{OH}) = 0.47 \pm 0.06$  at 193 nm, which is larger than the value reported by Turnipseed et al.<sup>20</sup> At 248 nm they report  $\Phi(\text{OH}) = 0.75 \pm 0.10$ , which is a smaller value than reported in other studies.

Felder et al.<sup>6</sup> used molecular beam/photofragment translational spectroscopy and reported the yield for  $(\text{OH} + \text{NO}_2)$  to be  $\Phi(\text{OH}) = 0.6 \pm 0.1$  and for  $(\text{O} + \text{HONO})$  to be  $\Phi(\text{HONO}) = 0.4 \pm 0.1$  at 193 nm. Myers et al.<sup>13</sup> also used this technique to measure the primary processes in the photolysis at 193 nm from the different photofragment ions and found evidence for all channels except 4. They determined the branching ratio  $(\text{OH} + \text{NO}_2)/(\text{O} + \text{HONO})$  to be  $0.50 \pm 0.05$ ,  $\Phi(\text{OH}) = 0.33 \pm 0.04$  (in excellent agreement with the value obtained by Turnipseed et al.<sup>20</sup>). They also reported  $\Phi(\text{O}({}^3\text{P}) + \text{O}({}^1\text{D})) = 0.67 \pm 0.04$ , which is lower than the  $0.81 \pm 0.13$  value reported by Turnipseed et al.<sup>20</sup> but the latter authors included the contribution of the secondary dissociation of  $\text{NO}_2$  produced in channel (1). Their primary yield of  $\text{O}({}^1\text{D})$  formation of  $0.54 \pm 0.04$  is much larger than the  $\Phi(\text{O}({}^1\text{D}))$  yield of  $0.28 \pm 0.07$  measured by Turnipseed et al.<sup>20</sup> and this discrepancy remains unexplained. In a study using LIF and REMPI–TOF techniques, Li et al.<sup>10</sup> found evidence for the  $(\text{O}({}^3\text{P}) + \text{HONO})$  channel with a yield of  $\sim 0.06$ .

Band strengths for the OH stretch vibrational overtones of  $\text{HNO}_3$  have been reported by Donaldson et al.,<sup>5</sup> Zhang et al.,<sup>21</sup> and Brown et al.<sup>2</sup> Photodissociation of  $\text{HNO}_3$  by excitation of the  $3\nu_{\text{OH}}$  (~983 nm),  $4\nu_{\text{OH}}$  (~755 nm) and  $5\nu_{\text{OH}}$  (~618 nm) overtones is a possible source of atmospheric OH radicals. There is good agreement among the various studies. Band strengths (in units of  $10^{-20} \text{ cm}^2 \text{ molecule}^{-1} \text{ cm}^{-1}$ ) of 2.63 for  $3\nu_{\text{OH}}$  and 0.237 for  $4\nu_{\text{OH}}$  were reported by Donaldson et al.<sup>5</sup> Zhang et al.<sup>21</sup> obtained band strengths of  $(2.9 \pm 0.7)$  for  $3\nu_{\text{OH}}$  and  $(0.28 \pm 0.10)$  for  $4\nu_{\text{OH}}$ . Brown et al.<sup>2</sup> measured the band strengths for  $4\nu_{\text{OH}}$  to be  $(0.225 \pm 0.015)$  at 296 K and  $(0.223 \pm 0.015)$  at 251 K and for  $5\nu_{\text{OH}}$  to be  $(0.0257 \pm 0.015)$  at 296 K and  $(0.0241 \pm 0.035)$  at 251 K. Although the contribution to the overall atmospheric OH production rate from  $\text{HNO}_3$  overtone photodissociation is small, it is larger than estimated by Donaldson et al.<sup>4</sup>

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

**Absorption Cross Sections:** The gas-phase UV absorption spectrum of peroxy nitric acid, HO<sub>2</sub>NO<sub>2</sub>, has been reported by Cox and Patrick<sup>1</sup> (195–265 nm; 284 K), Morel et al.<sup>9</sup> (200–290 nm; 298 K), Graham et al.<sup>3</sup> (190–330 nm; 269 K), Molina and Molina<sup>8</sup> (190–330 nm; 298 K), Singer et al.<sup>13</sup> (210–329 nm; 253, 273, and 298 K), and Knight et al.<sup>5</sup> (220–350 nm; 273, 296, 318, and 343 K). There is very good agreement (to within 5%) between the results of Molina and Molina<sup>8</sup> and Singer et al.<sup>13</sup> over the range 210–290 nm, but differences of ~15–60% exist in the wavelength range critical for atmospheric photodissociation ( $\lambda \geq 290$  nm). The cross section values from Cox and Patrick,<sup>1</sup> Graham et al.,<sup>3</sup> and Morel et al.<sup>9</sup> are systematically greater than those of Molina and Molina<sup>8</sup> at wavelengths >200 nm. Knight et al.<sup>5</sup> used the data of Molina and Molina<sup>8</sup> and Singer et al.<sup>13</sup> in the 250–270 nm region for normalization to provide absolute cross section data for the long wavelength region. The recommended room temperature absorption cross section data in Table 4C-18 are a combination of data from Molina and Molina<sup>8</sup> in the region 190–205 nm, the mean of the data from Molina and Molina<sup>8</sup> and Singer et al.<sup>13</sup> in the region 210–275 nm, and the data from Knight et al.<sup>5</sup> in the region 280–350 nm.

The temperature dependence of the absorption spectrum was examined by Singer et al.,<sup>13</sup> who found no temperature dependence between 253 and 298 K, and by Knight et al.,<sup>5</sup> who reported a systematic increase of the absorption cross sections with increasing temperature. Knight et al.<sup>5</sup> parameterized the temperature dependence using a two component model

$$\sigma(T, \lambda) = \sigma_0(\lambda)/Q + \sigma_1(\lambda)(1 - 1/Q)$$

where the partition function is given by  $Q = 1 + \exp(-\Delta E/(0.69T))$  with  $\Delta E = 988 \text{ cm}^{-1}$  (O-O stretching vibration) and T is in K. The Knight et al. parameterization is recommended.

On the basis of the results from the Molina and Molina, Singer et al., and Knight et al. studies, an uncertainty factor for the HO<sub>2</sub>NO<sub>2</sub> room temperature absorption cross sections in the wavelength region 190–350 nm, is estimated to be 1.2 (2σ). The uncertainty factor at temperatures <298 K is expected to be greater in the long wavelength region, but is difficult to estimate without additional studies.

*Photolysis Quantum Yield and Product Studies:* HO<sub>2</sub>NO<sub>2</sub> photodissociates in the UV with a unit quantum yield. MacLeod et al.<sup>6</sup> measured the quantum yield of OH radicals at 248 nm as  $\Phi(\text{OH}) = 0.34 \pm 0.16$  (the sum of channels 2 and 5), relative to the OH yield in the photolysis of H<sub>2</sub>O<sub>2</sub>. Roehl et al.<sup>10</sup> determined the quantum yield of NO<sub>2</sub> in the photolysis at 248 nm (relative to the NO<sub>2</sub> yield in the photolysis of HNO<sub>3</sub>) to be  $\Phi(\text{NO}_2) = 0.56 \pm 0.17$  (the sum of channels 1,4 and 5). Jimenez et al.<sup>4</sup> measured the yield of OH and HO<sub>2</sub> (from channels 1 and 6) at 193 and 248 nm (relative to the photolysis of H<sub>2</sub>O<sub>2</sub>) and the yield of NO<sub>3</sub> (relative to the photolysis of ClONO<sub>2</sub>) at 193, 248 and 308 nm over a pressure range of 10 to 84 Torr. Jimenez et al.<sup>4</sup> reported  $\Phi_{193}(\text{OH}) = 0.21 \pm 0.12$ ,  $\Phi_{248}(\text{OH}) = 0.085 \pm 0.08$ ,  $\Phi_{193}(\text{HO}_2) = 0.56 \pm 0.02$ ,  $\Phi_{248}(\text{HO}_2) = 0.89 \pm 0.26$ ,  $\Phi_{193}(\text{NO}_3) = 0.35 \pm 0.03$ ,  $\Phi_{248}(\text{NO}_3) = 0.08 \pm 0.03$  and  $\Phi_{308}(\text{NO}_3) = 0.05 \pm 0.02$ . Assuming that only channel (2) contributes to OH and NO<sub>3</sub> production, these results imply that at 248 nm the yields of OH and NO<sub>3</sub> are nearly identical, 0.08. This lower yield is in disagreement with the earlier 248 nm results of MacLeod et al.<sup>6</sup> and Roehl et al.<sup>10</sup> The high HO<sub>2</sub> yield ( $0.89 \pm 0.26$ ) measured at 248 nm by Jimenez et al.<sup>4</sup> overlaps within the experimental uncertainties with the NO<sub>2</sub> yield ( $0.56 \pm 0.17$ ) of Roehl et al.,<sup>10</sup> assuming that the HO<sub>2</sub> arises from channel (1). It cannot however not be excluded that the difference in NO<sub>2</sub> yields reflects the contribution of channel (6). The recommended quantum yields are given in Table 4C-19 where the values below 200 nm are taken from Jimenez et al.<sup>4</sup> and the values above 200 nm represent an average of the results from Jimenez et al., Roehl et al. and MacLeod et al. The estimated uncertainty in the recommended quantum yields is ±0.2.

The photodissociation of HO<sub>2</sub>NO<sub>2</sub> via excitation of the OH stretch vibrational overtones 2v<sub>1</sub>, 3v<sub>1</sub>, and 4v<sub>1</sub> in the near IR and visible is a possible atmospheric HO<sub>x</sub> source.<sup>15 12 2</sup> The band strengths (in units of  $10^{-20} \text{ cm}^2 \text{ molecule}^{-1} \text{ cm}^{-1}$ ) of ( $3.8 \pm 0.11$ ) for 3v<sub>1</sub> and ( $0.30 \pm 0.18$ ) for 4v<sub>1</sub> have been reported by Zhang et al.<sup>16</sup> and ( $3.3 \pm 0.7$ ) for 3v<sub>1</sub> by Roehl et al.<sup>11</sup> Stark et al.<sup>14</sup> report greater values for the 3v<sub>1</sub> and 4v<sub>1</sub> band strengths of ( $5.7 \pm 1.1$ ) and ( $0.49 \pm 0.09$ ), respectively. Roehl et al.<sup>11</sup> also measured absolute integrated band strengths and photodissociation quantum yields for 3 dissociative bands in the infrared region: 2v<sub>1</sub> + v<sub>3</sub> ( $8242 \text{ cm}^{-1}$ ), 2v<sub>1</sub> ( $6900 \text{ cm}^{-1}$ ) and v<sub>1</sub> + 2v<sub>3</sub> ( $6252 \text{ cm}^{-1}$ ) as a function of temperature. Matthews et al.<sup>7</sup> photolysed HO<sub>2</sub>NO<sub>2</sub> at 390 nm in its first OH-stretching overtone (2v<sub>1</sub>) and reported a quantum yield of 0.30 at 298 K. The temperature dependent cross sections and dissociation quantum yields from Roehl et al.<sup>11</sup> are summarized in Table 4C-20.

**Table 4C-18. Recommended Absorption Cross Sections of HO<sub>2</sub>NO<sub>2</sub> at 298 K**

## SECTION 4D. ORGANIC PHOTOCHEMISTRY

### D1. CH<sub>4</sub> (methane)

[Back to Index](#)

(New Entry)

*Absorption Cross Sections.* CH<sub>4</sub> (methane) has negligible UV absorption. Its VUV absorption spectrum has been extensively studied at and around Lyman- $\alpha$ , 121.567 nm, including studies by Watanabe et al.<sup>15</sup> (120–144 nm), Ditchburn<sup>6</sup> (27–151 nm), Sun and Weissler<sup>13</sup> (37–131 nm), Laufer and McNesby<sup>9</sup> (113–143 nm), Backx et al.<sup>2</sup> (13.8–144 nm), Mount et al.<sup>12</sup> (137–160 nm), Lee and Chiang<sup>11</sup>, Lee et al.<sup>10</sup> (120–153 nm), Au et al.<sup>1</sup> (5.6–165 nm), Brownsword et al.<sup>3</sup> (121.6 nm), Vatsa and Volpp<sup>14</sup> (121.567 nm), Kameta et al.<sup>7</sup> (52–125 nm), and Chen and Wu<sup>5</sup> (120–142 nm). The measured or interpolated values are in reasonable agreement at 121.567 nm, to within 20%. The recommended Lyman- $\alpha$  cross section at 298 K, adopted from Chapter 3<sup>4</sup> in the SPARC<sup>8</sup> (2013) lifetime report, is  $1.85 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  with an uncertainty factor of 1.3 (2σ).

## D2. CH<sub>2</sub>O (formaldehyde)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections.* The UV absorption spectrum of formaldehyde (CH<sub>2</sub>O) displays a highly structured absorption band (the formally electric-dipole forbidden S<sub>1</sub> ← S<sub>0</sub> transition gives rise to the Ã<sup>1</sup>A<sub>2</sub> – X<sup>1</sup>A<sub>1</sub> band system, which becomes allowed through vibronic coupling) between 240 and 380 nm. The absorption spectrum of formaldehyde has been measured in many studies at temperatures between 222 and 353 K as summarized in Table 4D-1.

**Table 4D-1. Summary of CH<sub>2</sub>O Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength range (nm)	Resolution (nm)	Medium
McMillan <sup>5</sup>	1966	348	202–374	1	air
McQuigg and Calvert <sup>22</sup>	1969	300	220–370	1	air
Calvert et al. <sup>4</sup>	1972	298	290–360	1	air
Bass et al. <sup>1</sup>	1980	223, 296	258–360	0.05	air
Moortgat et al. <sup>25</sup>	1980	285	215–370	0.5	air
Moortgat et al. <sup>26</sup>	1983	220–353	253–353	5	air
Cantrell et al. <sup>6</sup>	1990	223, 233, 243, 253, 263, 273, 283, 293, 296	300–385.8	1.0 cm <sup>-1</sup> (~0.011)	vacuum
Rogers <sup>31</sup>	1990	296	235–365	0.01–0.04	vacuum
Meller and Moortgat <sup>23</sup>	2000	223, 298	224–373	~0.025	air
Chen and Zhu <sup>8</sup>	2003	293	290–330	0.0014	
Bogumil et al. <sup>2</sup>	2003	293	247–400	0.25	air
Pope et al. <sup>29</sup>	2005	263, 294	313–320	0.1 cm <sup>-1</sup> (~0.001)	air/vacuum
Pope et al. <sup>30</sup>	2005	294	308–320	0.1 cm <sup>-1</sup>	air/vacuum
Co et al. <sup>11</sup>	2005	220, 298	351–356	0.0003	vacuum
Smith et al. <sup>32</sup>	2006	245, 294	300–340	0.0035	air/vacuum
Gratien et al. <sup>17</sup>	2007	296	240–370	0.15	air
Gratien et al. <sup>18</sup>	2007	294	300–360	0.18	air
Gorroxategi Carbajo et al. <sup>16</sup>	2008	245, 294	300–330	0.0035	air/vacuum
Tatum Ernst et al. <sup>35</sup>	2012	294 ± 2	304–330	0.09 cm <sup>-1</sup> (~0.001)	air

Meller and Moortgat<sup>23</sup> have reviewed the cross section studies prior to 2000 including descriptions of the techniques, experimental details of CH<sub>2</sub>O generation and the absorption measurements, and a comparison of the various results. The CH<sub>2</sub>O absorption cross sections are a strong function of the measurement resolution and this needs to be considered when comparing results from the various studies. Low resolution spectra were obtained by McMillan<sup>5</sup> and Moortgat et al.<sup>25</sup> whereas medium resolution measurements were reported by Bass et al.,<sup>1</sup> Rogers,<sup>31</sup> and Bogumil et al.<sup>2</sup> The spectrum reported by Cantrell et al.<sup>6</sup> was measured with a resolution of 0.011 nm over the 300–358 nm region in the temperature range 223–293 K using Fourier transform spectroscopy. Meller and Moortgat<sup>23</sup> reported a spectrum at ~0.025 nm resolution over the entire UV absorption band (224–373 nm) at 298 and 223 K using diode array spectroscopy. In general, the agreement between the medium and higher resolution data is good, although the cross section data of Bass et al.<sup>1</sup> and Rogers<sup>31</sup> are systematically lower than those of Meller and Moortgat<sup>23</sup>. The spectrum reported by

Bogumil et al.<sup>2</sup> that was obtained using the SCIAMACHY pre-flight satellite instrument agrees with the data of Meller and Moortgat.<sup>23</sup> The low resolution absorption cross sections reported by Chen and Zhu<sup>7,8</sup> and Chen et al.<sup>9</sup> in the 280–330 nm region deviate substantially, up to 50%, from those reported by Meller and Moortgat.<sup>23</sup>

A high resolution CH<sub>2</sub>O spectrum, near the Doppler broadening limit of 0.07 cm<sup>-1</sup>, was measured by Pope et al.<sup>29,30</sup> in the range 308–320 nm using tunable UV laser absorption spectroscopy at 263 and 294 K. In a later study from the same laboratory, Smith et al.<sup>32</sup> extended the high resolution measurements (0.35 cm<sup>-1</sup>) from 300 to 340 nm at 294 and 245 K. The high resolution CH<sub>2</sub>O spectrum measured by Pope et al.<sup>29,30</sup> is in excellent agreement with the spectral features reported by Cantrell et al.<sup>6</sup> and Meller and Moortgat<sup>23</sup> after convolution with the lower resolution instrument functions. Rotationally resolved absorption cross sections in the narrow spectral region 351–356 nm were measured by Co et al.<sup>11</sup> using Fourier Transform spectroscopy with an apodized resolution of 0.027 cm<sup>-1</sup>. They observed a strong pressure dependence of the rotational lines over the pressure range 75 to 400 Torr and determined a pressure broadening coefficient in dry air of  $1.8 \times 10^{-4}$  cm<sup>-1</sup> Torr<sup>-1</sup> for several isolated lines in the 2<sup>0</sup>4<sup>1</sup><sub>0</sub> band.

Gratien et al.<sup>17,18</sup> measured UV (0.15 nm resolution) and IR absorption cross sections simultaneously and compared the Integrated Band Intensities (IBI) of the main vibronic bands with previously published UV and IR data. The IBIs measured by Gratien et al.<sup>18</sup> in the region 300–360 nm compare well (within ~7%) with the IBI data derived from Meller and Moortgat<sup>23</sup> but are ~20% lower than the IBIs calculated from the Cantrell et al.<sup>6</sup> and Rogers<sup>31</sup> data. Gratien et al.<sup>18</sup> attribute the difference to the IR band strength given in the HITRAN database, which is based on the data from Cantrell et al.<sup>6</sup> In a second study, Gratien et al.<sup>17</sup> compared the IBIs of 9 different band sections in the 300 to 360 nm region with more recent studies. In general, the IBI data of Gratien et al.<sup>17</sup> are in excellent agreement (within 2%) with the high resolution results of Smith et al.<sup>32</sup> It was also shown that the IBI data for 8 band sections measured by Smith et al.<sup>32</sup> are 2 to 14% larger than the data of Meller and Moortgat.<sup>23</sup> The IBIs for the bands studied by Pope et al.<sup>29,30</sup> (313.5–316.5 and 316.5–319.7 nm) are 4 and 13% larger, respectively, than the data of Meller and Moortgat.<sup>23</sup> On the other hand the IBI for the 351.7–355.5 nm band studied by Co et al.<sup>11</sup> is 12% larger than the values of Cantrell et al.<sup>6</sup> and Rogers<sup>31</sup> but in excellent agreement with those of Meller and Moortgat<sup>23</sup> and Gratien et al.<sup>17</sup>

The study by Tatum Ernst et al.<sup>35</sup> used tunable UV laser absorption to measure the CH<sub>2</sub>O spectrum at high resolution (0.09 cm<sup>-1</sup>) over the wavelength range 304–330 nm at 294 K. Significant differences exist in the resolved line peak heights and depth between lines obtained in this study and the high resolution studies of Pope et al.,<sup>29,30</sup> and Smith et al.<sup>32</sup> (the Tatum Ernst et al. dataset shows greater spectrum structure). This leads to discrepancies in the band strengths between this work and previous high resolution studies that is not presently understood. Tatum Ernst et al.<sup>35</sup> estimate the cross section uncertainty in their study to be ~10% ( $1\sigma$ ).

In general, the consistency between the absorption cross section data of Smith et al.,<sup>32</sup> Gratien et al.,<sup>17</sup> and Pope et al.<sup>29,30</sup> in the range 300 to 360 nm demonstrate that the previously recommended absorption cross sections reported by Meller and Moortgat<sup>23</sup> are too low by about 7–10%. The presently recommended cross sections in Table 4D-2 where taken from Meller and Moortgat<sup>23</sup> averaged over 1 nm intervals and scaled up by 8%. Table 4D-3 includes the scaled data averaged over intervals used in atmospheric modeling. Higher resolution cross section data can be obtained from the (studies cited in Table 4D-1). The estimated cross section uncertainty is expected to be a function of wavelength and measurement resolution. The recommended uncertainty factor for the band strengths is estimated to be 1.1 (2 $\sigma$ ).

The temperature dependence of the CH<sub>2</sub>O absorption cross sections has been studied by Bass et al.,<sup>1</sup> Moortgat et al.,<sup>25</sup> Cantrell et al.,<sup>6</sup> Meller and Moortgat,<sup>23</sup> Pope et al.,<sup>29,30</sup> Co et al.,<sup>11</sup> and Smith et al.<sup>32</sup> (see Table 4D-1). Temperature effects are the strongest at the maximum of the absorption bands where the lower temperatures result in larger absorptions. This effect is reversed in the wings of the absorption bands where higher temperatures result in a higher absorption. A linear parameterization of the absorption cross section temperature dependence between 223 and 323 K was derived by Meller and Moortgat<sup>23</sup>

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K}) + \Gamma(\lambda) \times (T - 298)$$

Values of  $\Gamma(\lambda)$  from Meller and Moortgat<sup>23</sup> where scaled up by 8% and the values averaged over 1 nm intervals and intervals used in atmospheric modeling are listed in Table 4D-2 and Table 4D-3, respectively.

VUV absorption cross sections for the wavelength region 60–185 nm have been obtained by Gentieu and Mentall,<sup>14</sup> Mentall et al.,<sup>24</sup> and Glicker and Stief<sup>15</sup> using optical methods and by Cooper et al.<sup>12</sup> for the region 6–261 nm using (e,e) dipole spectroscopy.

*Photolysis Quantum Yields and Product Studies:* The quantum yield studies by McQuigg et al.<sup>22</sup> and Calvert et al.<sup>4</sup> established that over the wavelength range 290–360 nm the radical yield increases with decreasing wavelength. More precise wavelength dependent quantum yield studies using monochromatic light sources were performed by Lewis et al.,<sup>20</sup> Marling,<sup>21</sup> Horowitz and Calvert,<sup>19</sup> Clark et al.,<sup>10</sup> Moortgat et al.,<sup>27</sup> and Tang et al.<sup>34</sup> Moortgat and Warneck<sup>28</sup> and Moortgat et al.<sup>25,26</sup> measured the yields of CO and H<sub>2</sub> in air (giving  $\Phi_1(H + HCO)$  +  $\Phi_2(H_2 + CO)$  and  $\Phi_2(H_2 + CO)$ ) as a function of wavelength (253–353 nm) and pressure (380–800 Torr) at 300 K and 220 K. These studies showed that the yield of CO was essentially unity between 290 and 330 nm at all pressures with no systematic temperature dependence. For  $\lambda > 330$  nm, both temperature and pressure have a significant effect on  $\Phi_2(H_2 + CO)$  but a negligible effect on  $\Phi_1(H + HCO)$ . At  $\lambda < 290$  nm the total CO yield was found to decrease to a value of 0.76 at 240 nm.

Smith et al.<sup>33</sup> measured relative quantum yields at 50 mbar for the production of the radical products H and HCO using NO-chemical amplification and subsequent detection of NO<sub>2</sub> with chemical ionization mass spectrometry. These authors measured the quantum yields in the range 269 to 339 nm with sufficient resolution ( $\pm 0.62$  nm) to observe structure in the wavelength dependence, that was previously unreported, that is believed to provide evidence for a competition among the various dissociation pathways. The measured  $\Phi_1(H + HCO)$  yields were normalized to a value of 0.753 at 303.75 nm based on the JPL 97-4 recommendation<sup>13</sup> and agree with the previous determinations reported by Horowitz and Calvert<sup>19</sup> and Moortgat et al.<sup>26</sup> However at  $\lambda > 320$  nm the  $\Phi_1(H + HCO)$  yields reported by Smith et al.<sup>33</sup> are larger than the values recommended by DeMore et al.<sup>13</sup> resulting in a larger (~8%) overall rate of radical production.

Pope et al.<sup>29,30</sup> and Gorrotxategi Carbajo et al.<sup>16</sup> used cavity ring-down spectroscopy to measure HCO radical absorption coefficients and CH<sub>2</sub>O absorption cross sections from which absolute HCO quantum yields were calculated. The absolute HCO radical signal was calibrated against the HCO radical produced from the Cl + HCHO → HCO + Cl<sub>2</sub> reaction following the photolysis of Cl<sub>2</sub>/CH<sub>2</sub>O/N<sub>2</sub> mixtures. In the 303–309 nm range  $\Phi_{HCO} \sim 0.6 \pm 0.1$  was obtained which is 25% lower than the JPL 06-2 recommendation and the data reported by Smith et al.<sup>33</sup> In the wavelength range 314–330 nm the  $\Phi_{HCO}$  values (0.06 to 0.11) agree to within the quoted uncertainties with the JPL 06-2 recommendation.

The experimental technique used by Gorrotxategi Carbajo et al.<sup>16</sup> measured the product of the high resolution absolute absorption cross section (identical as measured by Smith et al.<sup>32</sup>) and the absolute HCO quantum yield,  $\Phi_{HCO}(\lambda)\sigma_{CH_2O}(\lambda)$ , in the interval 302.6–331.0 nm with a wavelength resolution of 0.005 nm. It is important to note that a separate calculation of the product  $\Phi_{HCO}\sigma_{CH_2O}$  using single data of  $\Phi_{HCO}$  and  $\sigma_{CH_2O}$  at a given wavelength result in much lower  $\Phi_{HCO}\sigma_{CH_2O}$  values (up to a factor 2) than obtained by the direct combined technique.

Tatum Ernst et al.<sup>36</sup> used pulsed laser photolysis combined with pulsed laser induced fluorescence detection of OH radicals (conversion of H + HCO to OH by reaction with NO<sub>2</sub>) to determine a high resolution action spectrum, i.e., the product of the CH<sub>2</sub>O cross section and H + HCO quantum yield, over the wavelength range 304 to 329 nm.  $\Phi_1(H + HCO)$  yields were determined using the CH<sub>2</sub>O cross section data reported in Tatum Ernst et al.<sup>36</sup> and an absolute value of 0.69 at 31750 cm<sup>-1</sup>. The quantum yields for the individual absorption bands in this region are in reasonable agreement with previous determinations and earlier JPL recommendations, although differences between individual absorption bands that were not noted in previous studies were reported.

Troe<sup>37</sup> used theoretical calculations to evaluate the quantum yields for the molecular and radical photolysis processes at  $\lambda > 310$  nm. An analytical representation was provided that enables extrapolation into temperature and pressure ranges that are not easily accessible experimentally.

The recommended quantum yields at standard pressure (1 atmosphere) and 300 K are listed in Table 4D-4 are based on a polynomial fit over the wavelength range 250–338 nm of the data for  $\Phi_1(H + HCO)$  from Lewis et al.,<sup>20</sup> Marling,<sup>21</sup> Horowitz and Calvert,<sup>19</sup> Clark et al.,<sup>10</sup> Tang et al.,<sup>34</sup> Moortgat et al.,<sup>26</sup> Smith et al.,<sup>33</sup> Pope et al.,<sup>29,30</sup> Gorrotxategi Carbajo et al.,<sup>16</sup> and Tatum Ernst et al.<sup>36</sup>

$$\Phi_1(H + HCO) = a_0 + a_1\lambda + a_2\lambda^2 + a_3\lambda^3 + a_4\lambda^4$$

where

$$a_0 = 557.95835182$$

$$a_1 = -7.31994058026$$

$$a_2 = 0.03553521598$$

$$a_3 = -7.54849718 \times 10^{-5}$$

$$a_4 = 5.91001021 \times 10^{-8}$$

$\Phi_2(\text{H}_2 + \text{CO})$  was optimized using the quantum data for CO from Moortgat et al.<sup>26</sup> and the relation  $\Phi_2(\text{H}_2 + \text{CO}) = \Phi_{\text{tot}} - \Phi_1(\text{H} + \text{HCO})$ . The pressure and temperature dependence of  $\Phi_2(\text{H}_2 + \text{CO})$  for wavelengths >330 nm is based on the algorithm cited in Calvert et al.<sup>3</sup> The pressure dependence of  $\Phi_2(\text{H}_2 + \text{CO})$  is represented in Stern-Volmer form

$$\Phi_2(\text{H}_2 + \text{CO}) = \frac{1}{\frac{1}{(1 - \Phi_1(\lambda))} + \alpha(\lambda, T) \times P}$$

where pressure, P, is in atmospheres and  $\alpha(\lambda, T)$  is the quenching coefficient whose values at 300 K are calculated from  $\Phi_1$  and  $\Phi_2$

$$\alpha(\lambda, 300 \text{ K}) = \frac{1}{\Phi_2(\lambda, 300 \text{ K})} - \frac{1}{(1 - \Phi_1(\lambda))}$$

At temperatures between 220 and 300 K the quenching coefficient  $\alpha(\lambda, T)$  can be calculated using

$$\alpha(\lambda, T) = \alpha(\lambda, 300 \text{ K}) \times \left[ 1 + 0.05 \times (\lambda - 329) \times \left( \frac{(300 - T)}{80} \right) \right]$$

The formulae given above for the pressure and temperature dependence of the quantum yields are recommended.

### D3. CH<sub>3</sub>CHO (acetaldehyde)

[Back to Index](#)

CH <sub>3</sub> CHO + hν	→ CH <sub>3</sub> + HCO	357 kJ mol <sup>-1</sup>	335 nm	(1)
	→ CH <sub>4</sub> + CO	-19 kJ mol <sup>-1</sup>	All	(2)
	→ CH <sub>3</sub> CO + H	374 kJ mol <sup>-1</sup>	320 nm	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of acetaldehyde, CH<sub>3</sub>CHO, has been measured at room temperature by McMillan<sup>4</sup> (200-345 nm), Meyrahn et al.<sup>14</sup> (221-345 nm), Schneider and Moortgat<sup>15</sup> (197-362 nm), Libuda et al.<sup>8,9</sup> (235-360 nm), Martinez et al.<sup>12</sup> (202-365 nm), Limão-Vieira et al.<sup>10</sup> (240-350 nm), and Weaver et al.<sup>16</sup> (290-355 nm). The spectrum at wavelengths >200 nm consists of an absorption band with a peak at 290 nm and diffuse vibrational structure (~12 maxima or shoulders) at wavelengths >260 nm. The agreement between the various cross section studies is very good, mostly 5% or better, except for the results from Meyrahn et al.,<sup>14</sup> which are lower by ~10% in the structured region around the absorption maximum. The recommended cross sections in Table 4D-5 are based on the data of Libuda et al.<sup>8,9</sup> (1 nm averages of 0.6 nm resolution data) and Martinez et al.<sup>12</sup> (4 nm averages of 0.5 nm resolution data at 202-278 nm and 1 nm averages at 280-360 nm), for which the agreement is within 5% between 255 and 325 nm.

Spectrum measurements in the VUV have been reported by Lake and Harrison<sup>7</sup> (150–180 nm), Luazeau and Sandorff<sup>11</sup> (118–189 nm), Brint et al.<sup>2</sup> (120–180 nm), and Limão-Vieira et al.<sup>10</sup> (113–200 nm).

**Photolysis Quantum Yield and Product Studies:** The photodissociation quantum yield of CH<sub>3</sub>CHO and the product quantum yields are wavelength and pressure dependent. Quantum yield measurements have been reported by Calvert and Pitts<sup>4</sup> and Weaver et al.<sup>16</sup> at isolated wavelengths between 290 and 332 nm. Quantum yields of CO, CH<sub>4</sub> and CO<sub>2</sub> were determined in the photolysis of trace concentrations of CH<sub>3</sub>CHO in air and N<sub>2</sub> in the spectral range 250–330 nm at 1 atmospheric pressure by Meyrahn et al.,<sup>14</sup> which allowed the determination of ( $\Phi_1 + \Phi_2$ ),  $\Phi_2$ , and  $\Phi_3$ . The product quantum yield pressure dependence was also investigated by Meyrahn<sup>13</sup> at 270, 303.4 and 313 nm. Horowitz et al.<sup>6</sup> and Horowitz and Calvert<sup>5</sup> measured the quantum yields of CO, CH<sub>4</sub> and H<sub>2</sub> formation at 290, 300, 313, 320 and 332 nm in the presence of various pressures of O<sub>2</sub> and CO<sub>2</sub> from which  $\Phi_1$  and  $\Phi_2$  were derived. There is evidence from the studies of Meyrahn et al.<sup>13,14</sup> and Horowitz et al.<sup>6</sup> that some CO<sub>2</sub> is formed from secondary reactions of the CH<sub>3</sub>CO radical that is produced in channel (3). The quantum yield for channel 3 was estimated to be 0.025 at 300 nm and to decrease to zero at 320 nm. Both Meyrahn et al.<sup>13,14</sup> and Horowitz et al.<sup>5,6</sup> observed a pressure dependence of the product yields, from which Stern-Volmer quenching coefficients were derived. These data were summarized by Calvert et al.<sup>3</sup>

The quantum yield recommendation given in Table 4D-6 for room temperature and atmospheric pressure are based on the evaluation by Atkinson and Lloyd<sup>1</sup> and the measurements by Horowitz and Calvert,<sup>5</sup> Meyrahn et al.,<sup>14</sup> and Meyrahn.<sup>13</sup>

#### D4. C<sub>2</sub>H<sub>5</sub>CHO (propionaldehyde)

[Back to Index](#)

C <sub>2</sub> H <sub>5</sub> CHO + hν → C <sub>2</sub> H <sub>5</sub> + HCO	351 kJ mol <sup>-1</sup>	341 nm	(1)
→ C <sub>2</sub> H <sub>6</sub> + CO	-8 kJ mol <sup>-1</sup>	All	(2)
→ C <sub>2</sub> H <sub>4</sub> + HCHO	129 kJ mol <sup>-1</sup>	926 nm	(3)
→ CH <sub>3</sub> + CH <sub>2</sub> CHO	343 kJ mol <sup>-1</sup>	349 nm	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of propionaldehyde (C<sub>2</sub>H<sub>5</sub>CHO, propanal) has been measured at room temperature by Lucazeau and Sandorfy<sup>5</sup> (118–190 nm), McMillan<sup>2</sup> (220–342 nm), and Martinez et al.<sup>6</sup> (262–365 nm). Absorption cross sections have also been reported for isolated wavelengths by Blacet and Crane<sup>1</sup> (187–313 nm), Heicklen et al.<sup>4</sup> (293–325 nm), and Chen and Zhu<sup>3</sup> (280–330 nm). The spectrum at wavelengths >200 nm consists of an absorption band with structured features (~9 maxima or shoulders) at wavelengths >260 nm and maximum absorption at 285 and 293 nm. The agreement between the results from Martinez et al.<sup>6</sup> and McMillan<sup>2</sup> is excellent, i.e., ≤5% differences, between 238 and 322 nm. At shorter (longer) wavelengths the differences increase to ~30% (~50%). The data points reported by Heicklen et al.<sup>4</sup> fit well to these studies although the value reported at 293 nm is 20% smaller. The cross sections reported at 5 nm intervals by Chen and Zhu<sup>3</sup> agree to within 10% with those reported by Martinez et al.,<sup>6</sup> except the data at 285 and 330 nm which are 20% and 30% larger. The recommended absorption cross sections listed in Table 4D-7 are taken from Martinez et al.<sup>6</sup> and are 4 nm averages of the 0.5 nm resolution data in the region 202–278 nm and 1 nm averages in the region 280–360 nm.

*Photolysis Quantum Yield and Product Studies:* Quantum yield measurements have been performed by Heicklen et al.<sup>4</sup> and Chen and Zhu.<sup>3</sup> Heicklen et al.<sup>4</sup> measured the quantum yield of HO<sub>2</sub> and C<sub>2</sub>H<sub>5</sub>O<sub>2</sub> radicals (in air bath gas) using laser photolysis at 294, 302, 312, and 325 nm combined with UV absorption to determine Φ<sub>1</sub>. Quantum yields of CO and C<sub>2</sub>H<sub>6</sub> were obtained in steady-state photolysis (at 254, 312, and 334 nm) experiments in O<sub>2</sub> where Φ<sub>1</sub> = Φ(CO) - Φ(C<sub>2</sub>H<sub>6</sub>) and Φ<sub>2</sub> = Φ(C<sub>2</sub>H<sub>6</sub>). A Stern-Volmer pressure dependence of the quantum yields was observed at all wavelengths, i.e., lower quantum yields at higher pressures. At atmospheric pressure, values of Φ<sub>1</sub> = 0.22, 0.89, 0.85, 0.50, 0.26, and 0.15 were derived at 254, 294, 302, 313, 325, and 334 nm, respectively. Heicklen et al.<sup>4</sup> reported Φ<sub>2</sub> = 0.33 for 254 nm photolysis and Φ<sub>2</sub> = 0 at longer wavelengths. The contribution of other primary processes (Φ<sub>3</sub> and Φ<sub>4</sub>) was found to increase at wavelengths <265 nm from earlier studies as cited in Calvert and Pitts.<sup>2</sup>

Chen and Zhu<sup>3</sup> measured the quantum yield of HCO radicals (Φ<sub>1</sub>) over the wavelength range 280–330 nm using time-resolved cavity ring-down spectroscopy with detection of HCO at 613.8 nm. The reported HCO yields are 0.85 ± 0.06 at 280 nm, 1.01 ± 0.07 at 285 nm, 0.95 ± 0.06 at 290 nm, 0.98 ± 0.06 at 295 nm, 0.92 ± 0.06 at 300 nm, 0.95 ± 0.08 at 305 nm, 0.98 ± 0.11 at 310 nm, 0.91 ± 0.05 at 315 nm, 1.08 ± 0.07 at 320 nm, 1.07 ± 0.14 at 325 nm, and 0.84 ± 0.08 at 330 nm. These values are quoted for zero-pressure but no pressure dependence to the HCO quantum yield at any wavelength was observed for pressures over the range 10–400 Torr N<sub>2</sub>.

The quantum yield studies by Heicklen et al.<sup>4</sup> and Chen and Zhu<sup>3</sup> are only in agreement in the narrow wavelength range 290–305 nm. At λ > 305 nm, the data of Chen and Zhu do not show the decrease of Φ<sub>1</sub> reported by Heicklen et al.<sup>4</sup> Because of the discrepancies between these data sets no quantum yield recommendation is given.

**D5. CH<sub>3</sub>O<sub>2</sub> (methylperoxy radical)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption cross sections of the methylperoxy radical, CH<sub>3</sub>O<sub>2</sub>, in the 195–310 nm region have been measured at room temperature by Parkes et al.,<sup>21</sup> Hochanadel et al.,<sup>8</sup> Parkes,<sup>20</sup> Anastasi et al.,<sup>2</sup> Kan et al.,<sup>11</sup> Cox and Tyndall<sup>3,4</sup> at 250 nm only; Adachi et al.,<sup>1</sup> Sander and Watson<sup>24</sup> at 250 nm only, Pilling and Smith<sup>22</sup> at 254 nm only, Kurylo et al.,<sup>12</sup> McAdam et al.,<sup>17</sup> Jenkin et al.,<sup>10</sup> Wallington et al.,<sup>27</sup> Moortgat et al.,<sup>18</sup> Dagaut and Kurylo,<sup>5</sup> Simon et al.,<sup>25</sup> Jenkin and Cox,<sup>9</sup> Lightfoot and Jemi-Alade<sup>14</sup> who measured the cross sections up to 777 K, Maricq and Wallington,<sup>16</sup> Wallington et al.,<sup>29</sup> Roehl et al.,<sup>23</sup> Fahr et al.,<sup>6</sup> and Nielsen et al.<sup>19</sup> The absorption cross sections have been evaluated in earlier reviews by Lightfoot et al.<sup>13</sup> and Wallington et al.,<sup>28</sup> who noted significant discrepancies in both the shapes of the spectra and the absolute magnitude of the cross section values. The ultraviolet absorption spectra have recently been

reevaluated by Tyndall et al.,<sup>26</sup> who fit the absorption spectra to a semi-logarithmic Gaussian distribution function suggested by Lightfoot et al.<sup>13</sup> and Maric et al.<sup>15</sup>

$$\sigma = \sigma_{\max} \exp^{-a \left[ \ln \left( \frac{\lambda_{\max}}{\lambda} \right) \right]^2}$$

Screening of the data suggested that most spectra published before 1987 did not constrain the shape of the spectrum very well as indicated by the large relative uncertainty of the width parameter a. The shape was determined by averaging the individual fitting parameters from McAdam et al.,<sup>17</sup> Moortgat et al.,<sup>18</sup> Simon et al.,<sup>25</sup> Lightfoot and Jemi-Alade,<sup>14</sup> Jenkin and Cox,<sup>9</sup> and Maricq and Wallington,<sup>16</sup> which were judged to be most reliable by Tyndall et al.<sup>26</sup> Absolute cross sections were based on relative measurements of absorption cross sections of CH<sub>3</sub>O<sub>2</sub> and C<sub>2</sub>H<sub>5</sub>O<sub>2</sub> at 240 nm taken under identical conditions (Wallington et al.,<sup>28</sup> Maricq and Wallington,<sup>16</sup> Fenter et al.,<sup>7</sup> and Roehl et al.<sup>23</sup>), combined with independent calibrations by Dagaut and Kurylo,<sup>5</sup> Simon et al.,<sup>25</sup> and Lightfoot and Jemi-Alade.<sup>14</sup> The fit parameters are:  $\sigma_{\max} = 4.26 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ ;  $a = 44.4$ ;  $\lambda_{\max} = 237.3 \text{ nm}$ . Table 4D-8 lists the recommended cross sections, which are taken from the review by Tyndall et al.<sup>26</sup> The shape of the UV spectrum measured by Nielsen et al.<sup>19</sup> is in excellent agreement with the recommendation of Tyndall et al.<sup>26</sup>

*Photolysis Quantum Yield and Product Studies:* The loss of CH<sub>3</sub>O<sub>2</sub> due to photolysis in the stratosphere and troposphere is expected to be negligible.

## D7. CH<sub>3</sub>CO (acetyl radical)

[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections.* The UV absorption spectrum of the acetyl radical, CH<sub>3</sub>CO, has been measured by Adachi et al.,<sup>1,2</sup> Parkes,<sup>7</sup> Anastasi and Maw,<sup>3</sup> Basco and Parmar,<sup>4</sup> Maricq and Szente,<sup>6</sup> and Cameron et al.<sup>5</sup> The spectrum has a very broad band in the range 190–270 nm with maximum near 215 nm. The shapes and magnitudes of the reported spectra differ substantially in the different studies. Adachi et al.<sup>1,2</sup> and Basco and Parmar<sup>4</sup> report a peak cross section of  $3.75 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  whereas Maricq and Szente<sup>6</sup> report a value of  $1.07 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 216 nm and Ansatsasi and Maw<sup>3</sup> a value of  $0.7 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 223 nm. Cameron et al.<sup>5</sup> measured a cross section of  $(1.4 \pm 0.2) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 220 nm. Cameron et al.<sup>5</sup> also measured the spectrum using diode array spectroscopy in the range 190–247 nm; the shape of the spectrum being in reasonable agreement with the spectrum measured by Maricq and Szente.<sup>6</sup> The spectrum by Cameron et al.<sup>5</sup> is given by the equation

$$\sigma = \sigma_{\max} \exp^{-a \left[ \ln \left( \frac{\lambda_{\max}}{\lambda} \right) \right]^2}$$

where

$$\sigma_{\max} = 1.549 \times 10^{-17} \quad a = 129.19 \quad \lambda_{\max} = 213.985$$

The visible absorption spectrum of CH<sub>3</sub>CO was measured by Rajakumar et al.<sup>8</sup> in the wavelength range 490–660 nm using cavity ring-down spectroscopy. The spectrum has a broad continuous band with a broad peak at 535 nm. The spectrum obtained with the H<sub>2</sub>O<sub>2</sub> photolysis source (in the presence of CH<sub>3</sub>CHO) was used as a reference and fit with an empirical polynomial expression

$$\sigma(\lambda) = A + B\lambda + C\lambda^2 + D\lambda^3 + E\lambda^4$$

yielding the parameters ( $\sigma$  in units of  $\text{cm}^2 \text{ molecule}^{-1}$ ,  $\lambda$  in nm)

$$\begin{array}{ll} A = -6.6124 \times 10^{-17} & D = 1.02141 \times 10^{-24} \\ B = 4.1946 \times 10^{-19} & E = -3.93411 \times 10^{-28} \\ C = -9.865 \times 10^{-22} & \end{array}$$

The recommended UV absorption cross sections in Table 4D-9 were calculated using the equation from Cameron et al.<sup>5</sup> The recommended cross sections in the visible region in Table 4D-10 were calculated using the polynomial expression from Rajakumar et al.<sup>8</sup>

**D8. CH<sub>3</sub>C(O)O<sub>2</sub> (acetylperoxy radical)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of the acetylperoxy radical, CH<sub>3</sub>C(O)O<sub>2</sub>, is continuous with two absorption bands in the 185–300 nm region. The band centered at 245 nm is overlapped by a stronger band that peaks near 207 nm. Absorption cross sections have been measured at room temperature by Addison et al.,<sup>1</sup> Basco and Parmer,<sup>2</sup> Moortgat et al.,<sup>5</sup> Maricq and Szente,<sup>4</sup> and Roehl et al.<sup>6</sup> The absorption cross sections have been evaluated in reviews by Lightfoot et al.,<sup>3</sup> Wallington et al.,<sup>8</sup> and Tyndall et al.<sup>7</sup> and significant discrepancies in the both the shapes of the spectra and the absolute magnitude of the cross section values have been noted. Tyndall et al.<sup>7</sup> fit the absorption spectrum reasonably well to the sum of two Gaussian shaped absorption bands

$$\sigma = \sigma_{\max 1} \exp^{-a_1 \left[ \ln \left( \frac{\lambda_{\max 1}}{\lambda} \right) \right]^2} + \sigma_{\max 2} \exp^{-a_2 \left[ \ln \left( \frac{\lambda_{\max 2}}{\lambda} \right) \right]^2}$$

The optimized fit parameters were determined by averaging the fit parameters from Maricq and Szente<sup>4</sup> and Roehl et al.,<sup>6</sup> which were judged to be the most reliable. It should be noted that the data from Maricq and Szente were adjusted for their overcorrection for the contribution of CH<sub>3</sub>O<sub>2</sub>. Absolute cross sections were based on relative measurements to the absorption cross sections of C<sub>2</sub>H<sub>5</sub>O<sub>2</sub> at 240 nm. The fitting parameters are

$$\begin{aligned}\sigma_{\max 1} &= 6.29 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1} & \sigma_{\max 2} &= 3.26 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1} \\ \lambda_{\max 1} &= 206.0 \text{ nm} & \lambda_{\max 2} &= 246.1 \text{ nm} \\ a_1 &= 168.0 & a_2 &= 64.2.\end{aligned}$$

The recommended absorption cross sections in Table 4D-8 are taken from the review by Tyndall et al.<sup>7</sup>

*Photolysis Quantum Yield and Product Studies:* The loss of CH<sub>3</sub>C(O)O<sub>2</sub> in the stratosphere and troposphere due to photolysis is expected to be negligible.

#### D9. CH<sub>3</sub>C(O)CH<sub>2</sub>O<sub>2</sub> (acetonylperoxy radical)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of the acetonylperoxy radical, CH<sub>3</sub>C(O)CH<sub>2</sub>O<sub>2</sub>, has been measured at room temperature by Cox et al.,<sup>2</sup> Bridier et al.,<sup>1</sup> and Nielsen et al.<sup>3</sup> The spectra from Cox et al.<sup>2</sup> and Nielsen et al.<sup>3</sup> are in good agreement but differ significantly from the spectrum reported by Bridier et al.<sup>1</sup> The spectrum reported by Cox et al.<sup>2</sup> and Nielsen et al.<sup>3</sup> exhibit two absorption features in the 200–340 nm region; a strong band at wavelengths <260 nm and a fairly weak band centered at 300 nm. Nielsen et al.<sup>3</sup> determined the cross section of the acetonylperoxy radical at 240 nm to be  $(2.03 \pm 0.22) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  relative to the well-established absorption cross section of CH<sub>3</sub>O<sub>2</sub>. The cross sections of Cox et al.,<sup>2</sup> renormalized to the absolute value at 240 nm of Nielsen et al.,<sup>3</sup> are recommended and listed in Table 4D-11.

*Photolysis Quantum Yields and Product Studies:* No recommendation.

**D10. CH<sub>3</sub>OOH (methylhydroperoxide)**[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CH<sub>3</sub>OOH (methylhydroperoxide) was measured at room temperature by Cox and Tyndall<sup>2</sup> (210–280 nm), Nozière et al.<sup>5</sup> (220–250 nm), Molina and Arguello<sup>4</sup> (210–350 nm), Vaghjiani and Ravishankara<sup>8</sup> (210–365 nm), Blitz et al.<sup>1</sup> (210–355 nm), Matthews et al.<sup>3</sup> (365–405 nm), and Roehl et al.<sup>6</sup> (305–365 nm).

Vaghjiani and Ravishankara<sup>8</sup> measured the cross sections of CH<sub>3</sub>OOH by monitoring the CH<sub>3</sub>OOH concentration via trapping and titration. These results are recommended and are listed in Table 4D-12. The earlier results of Molina and Arguello<sup>4</sup> are consistently 40% higher than the values shown in Table 4D-12. This difference is believed to be due to difficulty in trapping CH<sub>3</sub>OOH and measuring its concentration. The results of Blitz et al.<sup>1</sup> are consistently 30% smaller than the data of Vaghjiani and Ravishankara<sup>8</sup> in the range 225–325 nm and are unreliable above 325 nm due to baseline problems during their measurements. The absorption cross sections of Roehl et al.<sup>6</sup> determined using action spectroscopy are 8–21 % greater than those measured by Vaghjiani and Ravishankara.<sup>8</sup> Similar absorption measurements were performed by Matthews et al.<sup>3</sup> in the weak tail of the absorption band up to 405 nm. Their cross sections were normalized to the value of Vaghjiani and Ravishankara<sup>8</sup> at 355 nm and are included in the recommendation in Table 4D-12.

Matthews et al.<sup>3</sup> also measured the absorption of the  $5\nu_{\text{OH}}$  overtone band near 620 nm as  $(3.6 \pm 0.4) \times 10^{-24}$  cm<sup>2</sup> molecule<sup>-1</sup>.

*Photolysis Quantum Yields and Product Studies:* CH<sub>3</sub>OOH dissociates to give CH<sub>3</sub>O with unit quantum yield  $\Phi_1 = 1.00 \pm 0.18$  (Vaghjiani and Ravishankara<sup>9</sup>). These authors also observed some production of H (quantum yield of  $0.038 \pm 0.007$ ) and O atoms (quantum yield <0.007) at shorter wavelengths (i.e., 193 nm).

Thelen et al.<sup>7</sup> report unit quantum yields for OH production at 248 and 193 nm that are in agreement with the results of Vaghjiani and Ravishankara.<sup>8</sup> Quantum yields for OH and CH<sub>3</sub>O were also measured by Blitz et al.<sup>1</sup> in the wavelength range 223–355 nm. These authors have shown that the quantum yield for both OH and CH<sub>3</sub>O production is unity across this range of wavelengths.

## D11. HOCH<sub>2</sub>OOH (hydroxymethyl hydroperoxide)

[Back to Index](#)

(Recommendation: 10-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of hydroxymethyl hydroperoxide, HOCH<sub>2</sub>OOH, was measured at 298 K by Bauerle and Moortgat<sup>1</sup> in the range 205–360 nm, using a combination of diode array and FTIR spectroscopy. The absorption cross sections were also determined via action spectroscopy of the OH product by Roehl et al.<sup>3</sup> in the range 310–360 nm. The cross sections measured by Roehl et al.<sup>3</sup> were normalized to the value of Bauerle and Moortgat<sup>1</sup> at 320 nm. Their values are in reasonable agreement (within 20%) between 310 and 340 nm but are lower than those of Bauerle and Moortgat<sup>1</sup> at longer wavelengths (e.g. 33% at 350 nm). The recommended cross sections listed in Table 4D-13 are taken from Bauerle and Moortgat<sup>1</sup> in the range 205–305 nm, and from the average of the values of Bauerle and Moortgat<sup>1</sup> and Roehl et al.<sup>3</sup> for the region 310–380 nm.

*Photolysis Quantum Yields and Product Studies:* The photolysis process is assumed to occur with unity quantum yield,  $\Phi_1$ , at wavelengths greater than 290 nm, in analogy with CH<sub>3</sub>OOH. Overtone photodissociation spectrum and quantum yields were obtained in the OH-stretching region for the  $4\nu_{\text{OH}}$  (centered at 750 and 738 nm for the OO–H and RO–H bands, respectively) and  $5\nu_{\text{OH}}$  (centered at 617 and 604 nm for the OO–H and RO–H bands, respectively) transitions by Fry et al.<sup>2</sup> Overtone photodissociation is not expected to be significant under atmospheric conditions.

**D12. CH<sub>3</sub>ONO (methylnitrite)**[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections.* The UV/vis absorption spectrum of methylnitrite (CH<sub>3</sub>ONO) extends over the wavelength range between 190 and 440 nm and has a strong continuous band in the UV (190–300 nm) with a maximum near 214 nm. A sharply banded region exists in the near UV/vis region (300–440 nm) with nine absorption peaks, the strongest at ~339 nm. The spectrum has been measured at room temperature by McMillan,<sup>1</sup> Taylor et al.,<sup>4</sup> and Maricq and Wallington<sup>2</sup> while single wavelength absorption measurements have been reported by Napier and Norrish<sup>3</sup> at 215 and 339 nm at 298 K and by Wiebe and Heicklen<sup>5</sup> at 366 nm for temperatures in the range 298–423 K. Good agreement exists among these studies for the shape of the UV part of the spectrum. However, a slight wavelength shift is apparent (up to 4 nm) in the peak absorptions measured by Taylor et al.<sup>4</sup> and McMillan.<sup>1</sup> Taylor et al.<sup>4</sup> reported the cross section at the short wavelength band maximum near 215 nm to be  $(4.59 \pm 0.58) \times 10^{-18}$  compared to  $4.97 \times 10^{-18}$  by Napier and Norrish,<sup>3</sup>  $4.2 \times 10^{-18}$  by McMillan,<sup>1</sup> and  $4.47 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  by Maricq and Wallington.<sup>2</sup> The cross section of  $(3.24 \pm 0.16) \times 10^{-19}$  measured by Taylor et al.<sup>4</sup> at  $339 \pm 1 \text{ nm}$  is in agreement with the values of  $3.4 \times 10^{-19}$  and  $3.1 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  reported by Napier and Norrish<sup>3</sup> and McMillan,<sup>1</sup> respectively. The spectrum measured by Taylor et al.<sup>4</sup> is recommended and listed in Table 4D-14.

*Photolysis Quantum Yields and Product Studies:* The quantum yield for the dissociation in the banded region (300–400 nm) was measured by Wiebe et al.<sup>6</sup> to be  $\Phi_1 = 0.76$  at 366 nm.

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of methylnitrate (CH<sub>3</sub>ONO<sub>2</sub>) displays a strong continuous band in the region (190–250 nm) and a weaker band in the range (250–345 nm). The spectrum was measured at room temperature by McMillan<sup>1</sup> (201–323 nm), Maria et al.<sup>3</sup> (235–305 nm), Taylor et al.<sup>7</sup> (190–330 nm), Roberts and Fajer<sup>5</sup> (270–330 nm), Libuda and Zabel<sup>2</sup> (235–345 nm) and by Rattigan et al.<sup>4</sup> (220–335 nm) over the range 233–294 K, and Talukdar et al.<sup>6</sup> (236–334 nm) over the range 240–360 K. Good agreement exists at wavelengths <240 nm between the absorption cross sections measured by Taylor et al.<sup>7</sup> and Rattigan et al.<sup>4</sup> In the wavelength range 240–340 nm there is good agreement between the measurements of Roberts and Fajer,<sup>5</sup> Libuda and Zabel,<sup>2</sup> Rattigan et al.,<sup>4</sup> and Talukdar et al.<sup>6</sup> The values of Taylor et al.<sup>7</sup> are consistently larger at λ >270 nm. Between 235 and 280 nm the absorption cross sections measured by Talukdar et al.<sup>6</sup> are nearly independent of temperature but for λ >290 nm the cross sections decrease with decreasing temperature. At 330 nm the cross sections decrease by almost a factor of two between 298 and 240 K. Talukdar et al.<sup>6</sup> parameterized the absorption cross section temperature dependence using the expression

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K}) \times \exp[B(\lambda)(T - 298)]$$

The absorption cross sections measured at 298 K by Taylor et al.<sup>7</sup> are recommended between 190 and 235 nm and those of Talukdar et al.<sup>6</sup> in the range 236–344 nm, Table 4D-15. The temperature dependence from Talukdar et al.<sup>6</sup> is recommended and the B(λ) coefficients are listed in Table 4D-15.

*Photolysis Quantum Yields and Product Studies:* The photodissociation quantum yield for CH<sub>3</sub>ONO<sub>2</sub> to produce NO<sub>2</sub> and CH<sub>3</sub>O was measured by Talukdar et al.<sup>6</sup> to be Φ<sub>1</sub> = 0.91 ± 0.20 at 248 nm. Upper limits for the other channels at 248 nm were determined to be Φ<sub>2</sub> < 0.05, Φ<sub>3</sub> < 0.005, Φ<sub>4+8</sub> < 0.1 and Φ<sub>5</sub> < 0.015 ± 0.01. It is expected that the quantum yield Φ<sub>1</sub> is unity at wavelengths >248 nm. Oxygen atoms were measured with a quantum yield of 0.65 ± 0.15 at 193 nm and <0.01 at 248 and 308 nm. Yang et al.<sup>8</sup> studied the photodissociation of jet-cooled CH<sub>3</sub>ONO<sub>2</sub> at 193 and 248 nm and found channel (1) to be the principal photolysis product channel with relative yields of 0.7 and 1 at 193 and 248 nm, respectively. They also reported an O(<sup>1</sup>D) yield of 0.3 at 193 nm.

#### D14. CH<sub>3</sub>O<sub>2</sub>NO<sub>2</sub> (methylperoxy nitrate)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of CH<sub>3</sub>O<sub>2</sub>NO<sub>2</sub> (methylperoxy nitrate) has been measured by Cox and Tyndall<sup>2</sup> (200–310 nm) at 275 K, Morel et al.<sup>3</sup> (200–290 nm) at 296 K, Sander and

Watson<sup>4</sup> (240–280 nm) at 298 K, and Bridier et al.<sup>1</sup> (200–280 nm) at 298 K. The spectrum has a strong absorption band below 225 nm and a moderate band at longer wavelengths. The reported cross sections are in reasonable agreement in the range 230–250 nm but scatter in the cross section data exists at both shorter and longer wavelengths. The recommended cross sections listed in Table 4D-16 are a smoothed average of the data from the four studies.

*Photolysis Quantum Yields and Product Studies:* No recommendation.

## D15. CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> (peroxyacetyl nitrate, PAN)

[Back to Index](#)

(Recommendation: 06-2, Note 10-6, Evaluated 10-6)

*Absorption Cross Sections.* The absorption cross sections of CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> (peroxyacetyl nitrate, PAN) have been measured at room temperature by Stephens<sup>10</sup> (220–450 nm), Senum et al.<sup>9</sup> (200–300 nm), Basco and Parmar<sup>1</sup> (210–250 nm), and Libuda and Zabel<sup>6</sup> (219–325 nm) and at 250, 273, and 298 K by Talukdar et al.<sup>11</sup> (196–350 nm). The studies are in reasonable agreement. The data of Talukdar et al.<sup>11</sup> and Libuda and Zabel<sup>6</sup> agree within 10% at wavelengths <300 nm. The data of Stephens<sup>10</sup> and Basco and Parmar<sup>1</sup> are greater by up to 20 and 45%, respectively. The Senum et al.<sup>9</sup> cross sections are systematically less than the data of Talukdar et al.<sup>11</sup> Libuda and Zabel<sup>6</sup> carried out simultaneous UV and IR studies that showed that their measured cross sections needed to be corrected for impurities that are transparent in the UV but contribute to the sample pressure in the absorption cell. The corrections were on the order of 20%. The recommended absorption cross sections listed in Table 4D-17 are taken from Talukdar et al.,<sup>11</sup> which are in good agreement

with those of Libuda and Zabel<sup>6</sup> but include a wider spectral coverage and temperature range. The uncertainties in the cross sections are estimated to be of the order of a factor of 2 in the long wavelength region but smaller at shorter wavelengths, decreasing to about 10% at 220 nm.

A systematic decrease of the absorption cross sections with decreasing temperature was observed by Talukdar et al.<sup>11</sup> The temperature dependence was parameterized using the expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T - 298)$$

The temperature coefficients  $B(\lambda)$  are listed in Table 4D-17.

*Photolysis Quantum Yields and Product Studies.* Photolysis quantum yields for the production of NO<sub>2</sub> and NO<sub>3</sub> at 248 nm were reported by Mazely et al.<sup>7,8</sup>:  $\Phi(\text{NO}_2, 248 \text{ nm}) = 0.83 \pm 0.09$  and  $\Phi(\text{NO}_3, 248 \text{ nm}) = 0.3 \pm 0.1$ . The NO<sub>3</sub> quantum yield was obtained relative to the unity NO<sub>3</sub> quantum yield in the photolysis of N<sub>2</sub>O<sub>5</sub> at 248 nm. However, this latter quantum yield was re-measured to be  $0.8 \pm 0.1$  by Harwood et al.,<sup>4</sup> so that the  $\Phi(\text{NO}_3, 248 \text{ nm})$  should be rescaled to 0.24. Quantum yields for the production of NO<sub>3</sub> in the photolysis of CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> at 248 and 308 nm were also measured by Harwood et al.<sup>5</sup>:  $\Phi(\text{NO}_3, 248 \text{ nm}) = 0.19 \pm 0.04$  and  $\Phi(\text{NO}_3, 308 \text{ nm}) = 0.41 \pm 0.10$ . Flowers et al.<sup>2</sup> studied the photolysis of PAN at 289 nm and detected NO<sub>3</sub> using cavity ring-down spectroscopy. They obtained  $\Phi(\text{NO}_3, 289 \text{ nm}) = 0.31 \pm 0.08$  relative to the unity NO<sub>3</sub> quantum yield in the photolysis of N<sub>2</sub>O<sub>5</sub> at that wavelength. In a second study, Flowers et al.<sup>3</sup> measured the wavelength dependence of  $\Phi(\text{NO}_3)$ : at 294 nm ( $0.29 \pm 0.07$ ), 299 nm ( $0.28 \pm 0.07$ ), 308 nm ( $0.28 \pm 0.05$ ), and 312 nm ( $0.39 \pm 0.07$ ). These results indicate that between 289 and 308 nm the NO<sub>3</sub> quantum yield is nearly constant with  $\Phi(\text{NO}_3) = 0.29 \pm 0.07$ . An increase of  $\Phi(\text{NO}_3)$  at longer wavelengths cannot be ruled out. The recommended quantum yields are  $\Phi(\text{NO}_2) = 0.7$  and  $\Phi(\text{NO}_3) = 0.3$  for  $\lambda > 300 \text{ nm}$ .

#### D16. C<sub>2</sub>H<sub>5</sub>C(O)O<sub>2</sub>NO<sub>2</sub> (peroxypropionyl nitrate, PPN)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption cross sections of C<sub>2</sub>H<sub>5</sub>C(O)O<sub>2</sub>NO<sub>2</sub> (peroxypropionyl nitrate, PPN) have been measured at room temperature by Senum et al.<sup>2</sup> (200–300 nm) and at 253, 273, and 296 K by Harwood et al.<sup>1</sup> (210–340 nm). The absorption spectrum shows monotonically decreasing absorption cross sections with increasing wavelength over the range 200–340 nm. The absorption cross sections reported by Harwood et al.<sup>1</sup> are larger than those reported by Senum et al.<sup>2</sup> over the common wavelength range by ~10% at 210 nm up to ~30% at 300 nm. A wavelength dependent systematic decrease of the absorption cross sections with decreasing temperature was reported by Harwood et al.<sup>1</sup> The temperature dependence was parameterized to the empirical expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 296 \text{ K}) + B(\lambda)(T - 296)$$

The recommended absorption cross sections and temperature coefficients in Table 4D-18 are taken from Harwood et al.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for the production of NO<sub>3</sub> in the photolysis of C<sub>2</sub>H<sub>5</sub>C(O)O<sub>2</sub>NO<sub>2</sub> at 248 and 308 nm were measured by Harwood et al.<sup>1</sup> to be Φ<sub>2</sub>(248 nm) = 0.22 ± 0.04 and Φ<sub>2</sub>(308 nm) = 0.39 ± 0.04.

### D17. CH<sub>2</sub>=CHCHO (propenal, acrolein)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV/vis absorption spectrum of acrolein (CH<sub>2</sub>=CHCHO, propenal) has been measured at room temperature by Gardner et al.<sup>1</sup> (227–380 nm), Magneron et al.<sup>3</sup> (192–431 nm), and Lee et al.<sup>2</sup> The UV spectrum displays a broad absorption band between 250 and 400 nm, which is structured at wavelengths above 360 nm. The results of both studies agree to within 10% between 298 and 370 nm (with a few exceptions at 352, 360, 362 and 368 nm). Below 298 nm the differences increase up to ~40% with decreasing wavelength, above 368 nm the differences increase with increasing wavelength up to ~100%. The recommended absorption cross sections in Table 4D-19 are the 2 nm averages from the high resolution data of Magneron et al.<sup>3</sup>

*Photolysis Quantum Yield and Product Studies:* The photodecomposition of CH<sub>2</sub>=CHCHO was studied by Gardner et al.<sup>1</sup> at 313 and 334 nm over the pressure range 26–760 Torr air. They found photolysis at high pressures to be very inefficient at both wavelengths but the photolysis quantum yield to increase at low

pressure. At 313 nm the quantum yield for photodissociation  $\Phi_d$  of acrolein was 0.0065 at 1 atm and 0.081 at 26 Torr. The pressure dependence was described by

$$1/(\Phi_d - 0.004) = 0.086 + 1.613 \times 10^{-17} [M]$$

for concentrations (M) between  $8 \times 10^{17}$  and  $2.6 \times 10^{19}$  molecule cm $^{-3}$ . The major products observed were CO and C<sub>2</sub>H<sub>4</sub>. Magneron et al.<sup>3</sup> used broadband photolysis (275–380 nm) of dilute mixtures of acrolein in air to study CH<sub>2</sub>=CHCHO photodissociation but did not observe any products using long-path FTIR spectroscopy. An effective quantum yield for photolysis  $\Phi_{\text{eff}} \leq 0.005$  nm was measured by Magneron et al.<sup>3</sup> in an outdoor smog chamber.

## D18. CH<sub>2</sub>=C(CH<sub>3</sub>)CHO (2-methylpropenal, methacrolein, MACR)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The VUV/UV absorption spectrum of methacrolein (2-methylpropenal, MACR), CH<sub>2</sub>=C(CH<sub>3</sub>)CHO, has been measured using diode array spectroscopy at room temperature by Meller (237–391 nm) (see Keller-Rudek et al.<sup>3</sup>), Raber and Moortgat<sup>5</sup> (331 nm), Gierczak et al.<sup>2</sup> (214, 250–395 nm), and Lee et al.<sup>4</sup> The spectrum exhibits a broad absorption band between 250 and 390 nm with vibrational structure above 310 nm. A detailed vibrational-electronic analysis was reported by Birge et al.<sup>1</sup> The reported spectra are in very good agreement in the region 261–351 nm where the agreement is between ~1 and 10%. At shorter wavelengths, <260 nm, the differences increase to nearly 100% at 250 nm and the cross sections from Gierczak et al.<sup>2</sup> are consistently greater than those of Meller<sup>6</sup> and Raber and Moortgat.<sup>5</sup> The cross sections at the peaks in the structured region reported by Meller<sup>6</sup> and Raber and Moortgat<sup>5</sup> are consistently higher than those measured by Gierczak et al.<sup>2</sup> presumably due to the higher resolution used. At the band maximum, Raber and Moortgat<sup>5</sup> reported  $\sigma(330.7 \text{ nm}) = 7.64 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  and Gierczak et al.<sup>2</sup> reported  $\sigma(331 \text{ nm}) = 7.2 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ . Gierczak et al.<sup>2</sup> also reported  $\sigma(213.86 \text{ nm}) = (2.21 \pm 0.11) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  (Zn lamp source). The 1 nm averages of the results from Gierczak et al.<sup>2</sup> and Meller<sup>6</sup> are

generally (with a few exceptions) within 20% of each other for wavelengths up to 376 nm. Above 380 nm, the results of Gierczak et al.<sup>2</sup> are larger with increasing wavelength by up to nearly 80% than the results of Meller.<sup>6</sup> A wavelength shift of ~1 nm toward longer wavelengths can be observed above 340 nm in the absorption spectrum of Gierczak et al.<sup>2</sup> when compared to the spectrum reported by Meller.<sup>6</sup> The recommended absorption cross sections listed in Table 4D-20 are from Gierczak et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* The photodissociation quantum yield for CH<sub>2</sub>=C(CH<sub>3</sub>)CHO at atmospherically relevant wavelengths is low. Quantum yields were measured by Raber and Moortgat<sup>5</sup> using broad band photolysis in the wavelength range 275–380 nm, and determination of the stable products (CO, CO<sub>2</sub>, HCHO, C<sub>2</sub>H<sub>4</sub>, C<sub>3</sub>H<sub>6</sub>, C<sub>2</sub>H<sub>2</sub>) by FTIR spectroscopy. An upper limit of 0.05 was reported at 760 Torr. Gierczak et al.<sup>2</sup> used GC and GC-MS detection of photolysis end-products to determined CH<sub>2</sub>=C(CH<sub>3</sub>)CHO quantum yields at 308 nm of 0.008 ± 0.001 and 0.005 ± 0.001 at 25 and 650 Torr total pressure, respectively. At 351 nm they reported quantum yields of 0.005 ± 0.002 and 0.003 ± 0.001 at 25 and 650 Torr, respectively. A value of Φ < 0.01 is recommended for wavelengths > 308 nm.

#### D19. CH<sub>3</sub>C(O)CH=CH<sub>2</sub> (methyl vinyl ketone, MVK)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of methyl vinyl ketone (MVK), CH<sub>3</sub>C(O)CH=CH<sub>2</sub>, has been measured at room temperature by Schneider and Moortgat (240–398 nm) (see Keller-Rudek et al.<sup>4</sup>), Raber and Moortgat<sup>5</sup> (235–400 nm), Fahr et al.<sup>2</sup> (160–260 nm), and Gierczak et al.<sup>3</sup> (216.86 nm and 250–395 nm). The absorption band peaking at ~330 nm displays some weak vibrational band structure, which is superimposed on a continuum envelope. A detailed vibrational-electronic analysis was reported by Birge et al.<sup>1</sup> The cross sections from Schneider and Moortgat are somewhat smaller around the band maximum at 334 nm (agreement within ~10% between 290 and 365 nm), and larger by up to 50% and smaller by up to ~60% in the short- and long-wavelength tails, respectively, than the results of Gierczak et al.<sup>3</sup> Gierczak et al.<sup>3</sup> reported σ(213.86 nm) = (6.6 ± 0.04) × 10<sup>-17</sup> cm<sup>2</sup> molecule<sup>-1</sup> (Zn lamp source). They also measured the spectrum at reduced temperatures (range 250–298 K), and observed a small increase in the peak cross section of <2% at 250 K. Fahr et al.<sup>2</sup> reported σ(193 nm) = (3.2 ± 0.2) × 10<sup>-17</sup> cm<sup>2</sup> molecule<sup>-1</sup>. The recommended absorption cross sections in Table 4D-21 are taken from Gierczak et al.<sup>3</sup>

*Photolysis Quantum Yield and Product Studies:* Product quantum yields were measured by Raber and Moortgat<sup>5</sup> using broadband photolysis in the range 275–380 nm combined with FTIR monitoring of the stable photolysis products (major CO, C<sub>3</sub>H<sub>6</sub> and HCHO; minor CO<sub>2</sub>, HCOOH, CH<sub>3</sub>OH, CH<sub>3</sub>COOH). They report a pressure dependent quantum yield with Φ = 0.05 at 760 Torr and Φ = 0.12 at 54 Torr. Fahr et al.<sup>2</sup> used laser photolysis at 193.3 nm and measured the direct formation of CH<sub>3</sub> radicals at 216.4 nm and final products. They report a quantum yield close to unity for the formation of CH<sub>3</sub> and CH=CH<sub>2</sub> radicals. Gierczak et al.<sup>3</sup> measured quantum yields for photolysis at 308, 337, and 351 nm by monitoring the disappearance of MVK. They reported Φ = 0.16 at 25 Torr and Φ = 0.04 at 760 Torr at 308 nm, Φ = 0.04 at 25 Torr and Φ = 0.01 at 760 Torr at 337 nm; and Φ = 0.01 independent of pressure at 351 nm. The quantum yield data were fit to the empirical Stern-Volmer type expression

$$\Phi(\lambda, P) = \exp[-0.055 (\lambda - 308)] / (5.5 + 9.2 \times 10^{-19} [\text{M}])$$

where λ is in nm and [M] in molecule cm<sup>-3</sup>. This parameterization is recommended.

**D20. HOCH<sub>2</sub>CHO (glycolaldehyde, hydroxyacetaldehyde)**
[Back to Index](#)

HOCH <sub>2</sub> CHO + hν	→ CH <sub>2</sub> OH + HCO	345 kJ mol <sup>-1</sup>	347 nm	(1)
	→ CH <sub>3</sub> OH + CO	6 kJ mol <sup>-1</sup>	1910 nm	(2)
	→ OH + CH <sub>2</sub> CHO	365 kJ mol <sup>-1</sup>	328 nm	(3)
	→ HOCH <sub>2</sub> CO + H	381 kJ mol <sup>-1</sup>	314 nm	(4)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption cross sections of HOCH<sub>2</sub>CHO (glycolaldehyde, hydroxyacetaldehyde) have been measured at room temperature by Bacher et al.<sup>1</sup> (205–335 nm), Magneron et al.<sup>3</sup> (210–330 nm), and Karunandan et al.<sup>2</sup> (210–335 nm). The spectrum consists of a strong absorption below 220 nm and a weaker absorption band centered near 280 nm with evidence of vibrational progressions. The measurements performed by Magneron et al.<sup>3</sup> were done at two different laboratories and are nearly identical but reveal significant differences compared to the spectrum measured by Bacher et al.,<sup>1</sup> being about 20% at the maximum. The spectrum measured by Karunandan et al.<sup>2</sup> is in excellent agreement with Magneron et al.<sup>3</sup> at the maximum near 282 nm and at longer wavelengths. At shorter wavelengths the cross sections are consistently larger than those measured by Magneron et al.<sup>3</sup> 15 % at 250 nm, 40% at 230 nm and 85% at the minimum near 226 nm. At 184.9 nm the cross section was measured as  $(3.85 \pm 0.2) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ . The average of the cross sections of Magneron et al.<sup>3</sup> and Karunandan et al.<sup>2</sup> are recommended and listed in Table 4D-22.

*Photolysis Quantum Yields and Product Studies:* The broad band photolysis (285 ± 25 nm) of glycolaldehyde in air performed by Bacher et al.<sup>1</sup> revealed an overall quantum yield  $\Phi > 0.5$ , relative to a quantum yield of  $\Phi = 0.3$  for the removal of acetone. Product studies by FTIR suggests that channel (1) is the major photolysis channel (65–80%), while channel (2) accounts to 15–20%, and channel (3) contributes up to 15%. The formation of channel (4) was suggested to produce HOCH<sub>2</sub>CO as a source for OH radicals, whose presence was indirectly invoked due the formation of glyoxal. Magneron et al.<sup>3</sup> also photolysed glycolaldehyde (broadband lamps 275–380 nm) and measured products by FTIR (CO, CO<sub>2</sub>, HCHO and CH<sub>3</sub>OH). They observed direct evidence for OH production via channel (3) using OH scavenger and OH tracer species and performed additional photolysis experiments where glycolaldehyde was used an OH source to measure rate constants for OH with a series of dienes. The contribution of channel (2) was estimated to be 10% and that of channels (1) + (2) to be 90%. No evidence was found for channel (4). Karunandan et al.<sup>2</sup> measured a quantum yield of OH formation at 248 nm of  $\Phi_3 = (7.0 \pm 1.5) \times 10^{-2}$ . On the basis of the combined product studies the following quantum yields are recommended:  $\Phi_1 = 0.83$ ,  $\Phi_2 = 0.10$  and  $\Phi_3 = 0.07$  in the range 248–328 nm.

**Table 4D-22. Recommended Absorption Cross Sections of HOCH<sub>2</sub>CHO at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

## D21. CH<sub>3</sub>C(O)CH<sub>3</sub> (acetone)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6; Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of acetone, CH<sub>3</sub>C(O)CH<sub>3</sub>, has been measured at room temperature by Lake and Harrison<sup>18</sup> (159–203 nm), Calvert<sup>8</sup> (200–300 nm), Meyrahn et al.<sup>20,21</sup> (220–368 nm), Schneider and Moortgat (196–366 nm) (see Röth et al.<sup>24</sup>), Hynes et al.<sup>14</sup> (253.7 nm and 260–360 nm), Martinez et al.<sup>19</sup> (202–335 nm), Gierczak et al.<sup>12</sup> (215–349 nm), Wollenhaupt et al.<sup>29</sup> (220–346 nm), and Yujing and Mellouki<sup>30</sup> (240–350 nm). Absorption cross sections have also been determined at isolated wavelengths by Braun et al.<sup>6</sup> (193 nm, also for CD<sub>3</sub>C(O)CD<sub>3</sub>), Seki and Okabe<sup>25</sup> (193 nm), Krasnoperov and Mehta<sup>17</sup> (216.51 nm), and Gierczak et al.<sup>13</sup> (184.9 nm, also for CD<sub>3</sub>C(O)CD<sub>3</sub>).

The spectrum below 200 nm is highly structured in the wavelength regions 160–170 nm and 180–195 nm. A broad absorption band was observed between 210 and 340 nm for which higher resolution measurements give evidence for band maxima at ~273 and ~278 nm. The reported absorption cross sections are in excellent agreement with the range of deviations being ≤8% in the 240–320 nm region. The absorption cross section at the spectrum maximum range between 5.2 × 10<sup>-20</sup> and 4.8 × 10<sup>-20</sup> cm<sup>2</sup> molecule<sup>-1</sup>. In the tails of the absorption band, the various data sets become more divergent with decreasing wavelength with differences of up to ~50% at 220 nm and with increasing wavelength up to more than 100% at 340 nm. The data measured by Meyrahn et al.<sup>20,21</sup> are systematically higher at wavelengths >320 nm than the other studies. The absorption cross sections from Martinez et al.,<sup>19</sup> Gierczak et al.,<sup>12</sup> Wollenhaupt et al.,<sup>29</sup> and Yujing and Mellouki<sup>30</sup> agree to within 2.5% in the region of the absorption maximum and to within 50% in the short and long wavelength tails of the band.

The absorption spectrum temperature dependence has been studied by Hynes et al.<sup>14</sup> (300–340 nm) over the range 261–362 K, Gierczak et al.<sup>12</sup> (215–349 nm) over the range 235–298 K, and Gierczak et al.<sup>13</sup> (184.9 nm, also for CD<sub>3</sub>C(O)CD<sub>3</sub>) over the range 222–296 K. The absorption spectrum has modest temperature dependence at wavelengths >270 nm with the cross sections decreasing with decreasing temperature. At shorter wavelengths the spectrum is essentially independent of temperature, the cross section changes by <5% between 298 and 235 K. Gierczak et al.<sup>12</sup> parameterized the temperature dependent cross sections using the expression

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K})[1 + c_1(\lambda)T + c_2(\lambda)T^2]$$

that was later superseded by Burkholder<sup>7</sup> using the expression

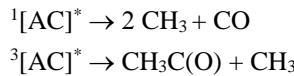

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K})[1 + A(\lambda)T + B_2(\lambda)T^2 + C(\lambda)T^3]$$

The recommended absorption cross sections at 298 K in Table 4D-23 are taken from Gierczak et al.<sup>12</sup> and the temperature coefficients A, B, and C derived by Burkholder.<sup>7</sup>

The absorption cross section of CH<sub>3</sub>C(O)CH<sub>3</sub> at 184.9 nm was observed to decrease very slightly with decreasing temperature between 296 and 222 K leading to an average value of (2.98 ± 0.10) × 10<sup>-18</sup> cm<sup>2</sup> molecule<sup>-1</sup>, whereas that of CD<sub>3</sub>C(O)CD<sub>3</sub> increased noticeably from 3.91 × 10<sup>-18</sup> cm<sup>2</sup> molecule<sup>-1</sup> (average of six results) at 295 K to 4.61 × 10<sup>-18</sup> cm<sup>2</sup> molecule<sup>-1</sup> at 232 K, as reported by Gierczak et al.<sup>13</sup>

*Photolysis Quantum Yield and Product Studies:* The UV photodissociation of acetone is wavelength, pressure, and temperature dependent. Since JPL 06-2 there has been a number of acetone photodissociation laboratory studies published [Khamaganov et al.<sup>15</sup> (248 and 266 nm), Khamaganov et al.<sup>16</sup> (248 nm and 266 nm), Nádasdia et al.<sup>22</sup> (248 nm and 308 nm), Rajakumar et al.<sup>23</sup> (248 nm), Somnitz et al.<sup>26,27</sup> (248 nm)]. The focus of these studies has been on the determination of the pressure and temperature dependence of the acetone loss and product (CH<sub>3</sub>, CH<sub>3</sub>CO, CO, and CO<sub>2</sub>) photolysis quantum yields as described further below.

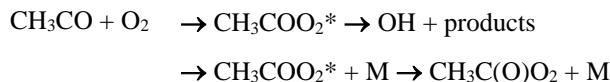

Gardner et al.<sup>11</sup> measured acetone loss ( $\Phi_{AC}$ ) and formation of the products CO<sub>2</sub>, CO, CH<sub>3</sub>OH and H<sub>2</sub>CO following the photolysis of dilute acetone-air mixtures at four wavelengths in the range 279–313 nm as a function of pressure (25–745 Torr) and temperature (271–301 K). At pressures >300 Torr, they observed a near constant quantum yield,  $\Phi_{AC} \approx \Phi_{CO_2} = \Phi_1 = 0.077$ , for photolysis wavelengths in the range 279–313 nm with a slight increase at lower pressures. Meyrahn et al.<sup>20,21</sup> measured the quantum yields of CO and CO<sub>2</sub> in the photolysis of dilute mixtures of acetone in air at nine wavelengths over the range 250–330 nm. At 1 atm,  $\Phi_{CO_2}$  decreased from 1.59 at 250 nm to 0.11 at 310 nm and increased to 0.27 at 330 nm.  $\Phi_{CO}$  decreased from 0.45 at 250 nm to 0.02 at 310 nm and increased to 0.09 at 330 nm. A CO<sub>2</sub> quantum yield larger than unity was explained to result from secondary reactions. Meyrahn et al.<sup>20,21</sup> measured the quantum yield of peroxyacetyl nitrate,  $\Phi_{PAN}$ , (which is assumed to be a direct measure of  $\Phi_1$ ) in the photolysis of acetone /air/NO<sub>2</sub> mixtures to decrease from ~0.78 in the region 250–260 nm to 0.03 at 330 nm. Meyrahn et al.<sup>20,21</sup> observed  $\Phi_{CO_2}$  to increase at lower pressures (Stern-Volmer mechanism) at 330 nm. Emrich and Warneck<sup>9,10</sup> also determined  $\Phi_{PAN}$  following the photolysis of acetone /air/NO<sub>2</sub> mixtures at six wavelengths between 280 and 330 nm at total pressures in the range 10–760 Torr. At 760 Torr,  $\Phi_{PAN}$  decreased from a value of 1.00 at 280 nm to 0.06 at 320 nm and increased to 0.13 at 330 nm. A Stern-Volmer type pressure dependence was observed at all wavelengths. The results were explained in terms of the rate of photodissociation from the excited singlet <sup>1</sup>[AC]<sup>\*</sup> state of acetone and the competing intersystem crossing to the triplet <sup>3</sup>[AC]<sup>\*</sup>, both relative to that of collisional quenching, as a function of energy above the dissociation threshold. It was proposed that

Gierczak et al.<sup>12</sup> determined  $\Phi_{AC}$  and  $\Phi_{CO_2}$  in the laser photolysis of acetone at nine wavelengths in the range 248–337 nm as a function of pressure (25–760 Torr, syn. air) and temperature (195–298 K). For photolysis wavelengths >270 nm,  $\Phi$  followed a Stern-Volmer type pressure dependence and the zero-pressure quantum yield was found to increase with decreasing wavelength to a value of unity near 290 nm. Gierczak et al.<sup>12</sup> observed a temperature dependence for the 308 nm quantum yield except for the lowest temperature included in their study, 195 K, and choose to report a temperature independent quantum yield. The studies of Blitz et al.<sup>4,5</sup> and Nádasdia et al.<sup>22</sup> have since reported temperature dependent quantum yields at 308 nm. The results from these studies are in good agreement. The Gierczak et al.<sup>12</sup> results are also in reasonable agreement. The Gierczak et al.<sup>12</sup> results at 298 K are nearly identical to those of Emrich and Warneck.<sup>9</sup> Gierczak et al.<sup>12</sup> and Warneck<sup>28</sup> have reported parameterizations for the quantum yields for the photodissociation of acetone dependence on wavelength and pressure.

Aloisio and Francisco<sup>1</sup> measured the quantum yield of acetone photodissociation at 248 and 308 nm in the presence and absence of water vapor. The apparent acetone quantum yield decreased from unity to  $0.73 \pm 0.07$  for 248 nm photolysis and from  $0.28 \pm 0.07$  to  $0.06 \pm 0.04$  for 308 nm photolysis with the addition of 9 Torr of H<sub>2</sub>O. Nádasdia et al.<sup>22</sup> performed a similar quantum yield study (with and without H<sub>2</sub>O) at 298 K and a total pressure of 133 mbar. They studied the effect for the same photolysis wavelengths and report quantum yields for the loss of acetone to be independent of H<sub>2</sub>O vapor to within their measurement accuracy;  $0.945 \pm 0.222$  (without H<sub>2</sub>O) and  $1.021 \pm 0.124$  (with 12 mbar H<sub>2</sub>O) at 248 nm and two sets of measurements at 308 nm using different acetone and H<sub>2</sub>O concentrations,  $0.342 \pm 0.028$  (without H<sub>2</sub>O) and  $0.319 \pm 0.018$  (with 12 mbar H<sub>2</sub>O) and  $0.308 \pm 0.024$  (without) and  $0.320 \pm 0.024$  (with 4 mbar H<sub>2</sub>O). There is no explanation for the apparent discrepancy between these studies.

Blitz et al.<sup>4,5</sup> reported the pressure and temperature (218–295 K) dependent quantum yields of acetone for photolysis wavelengths between 279 and 327.5 nm. Blitz et al.<sup>4,5</sup> used a spectroscopic technique to indirectly detect the formation of the CH<sub>3</sub>CO radical that is based on the detection of the OH radical formed in the reaction

The time-resolved studies of Blitz et al.<sup>4,5</sup> are more direct and sensitive than earlier studies. They observed “classical” Stern-Volmer behavior at  $\lambda < 302$  nm, but at  $\lambda > 302$  nm an extended form of the Stern-Volmer expression was necessary to fit their data for pressures below 15 Torr; reflecting the dissociation and quenching from both <sup>1</sup>[AC]<sup>\*</sup> and <sup>3</sup>[AC]<sup>\*</sup> excited states as described in Blitz et al.<sup>3</sup> On the basis of the low pressure quantum yield results at wavelengths >300 nm, Blitz et al.<sup>4,5</sup> determined that  $\Phi_{CH_3CO} = 0.65$  and  $\Phi_{CO} = 0.35$  at 248 nm from measurements made relative to this reference photolysis wavelength. Their analysis assumes that the acetone quantum yield in the low-pressure limit is unity in the long wavelength photolysis,

the acetone quantum yield at 248 nm is unity, and that the CH<sub>3</sub>CO quantum yield at 248 nm is independent of pressure. It has been established that the acetone quantum yield at 248 nm is unity and independent of temperature and pressure [Gierczak et al.,<sup>12</sup> Khamaganov et al.,<sup>16</sup> Aloisio and Francisco,<sup>1</sup> Nádasdia et al.,<sup>22</sup> and Somnitz et al.<sup>27</sup>]. Khamaganov et al.<sup>16</sup> also report that the acetone quantum yield is only weakly pressure dependent (60–760 Torr) at 266 nm. There is strong evidence now that the CH<sub>3</sub>CO, CH<sub>3</sub>, and CO quantum yields at 248 nm are, however, pressure dependent. For photolysis at 248 nm there is sufficient energy for the nascent energetically excited CH<sub>3</sub>CO radical to dissociate via a non-concerted step

or be collisionally quenched

Khamaganov et al.<sup>15</sup> (5–1500 Torr), Somnitz et al.<sup>26,27</sup> (20–900 mbar), and Rajakumar et al.<sup>23</sup> (60–670 Torr) reported pressure dependent quantum yields for CH<sub>3</sub>, CO and CO<sub>2</sub>, and CH<sub>3</sub>CO, respectively, over the range of pressures indicated. The results from these studies are in reasonable agreement and report low pressure quantum yields of  $\Phi(\text{CH}_3) = 1.42 \pm 0.15$  (Khamaganov et al.<sup>15</sup>),  $\Phi(\text{CO}) = 0.51$  (Somnitz et al.<sup>27</sup>), and  $\Phi(\text{CH}_3\text{CO}) = 0.535 \pm 0.09$  (Rajakumar et al.<sup>23</sup>). Somnitz et al.<sup>26,27</sup> have modeled the dissociation process using RRKM theory with a time-dependent master equation approach. The impact of a pressure dependence for the CH<sub>3</sub>CO quantum yield at 248 nm on the interpretation of the Blitz et al. quantum yield data at longer wavelengths is at present unclear.

At  $\lambda < 310$  nm and 1 atm, there was very good agreement with the data of Gierczak et al.<sup>12</sup> and Emrich and Warneck<sup>9</sup>; however at  $\lambda > 310$  nm, the measured quantum yields were significantly smaller. The temperature dependence of  $\Phi_{\text{TOTAL}}$  is quite striking at the longer wavelengths: the ratio of the quantum yields at 295 and 218 K reported by Blitz et al.<sup>4,5</sup> are  $\Phi_{\text{TOTAL}}(295 \text{ K}) / \Phi_{\text{TOTAL}}(218 \text{ K}) \approx 4$  and  $\approx 20$  at 310 nm and 322.5 nm, respectively.

A major difference in the study of Blitz et al.,<sup>4,5</sup> from several of the earlier studies is that the OH radicals are detected before undergoing secondary reactions, so that the OH yields represent the CH<sub>3</sub>CO radicals produced. The quantum yields reported from the Gierczak et al.<sup>12</sup> and Emrich and Warneck<sup>9</sup> studies were based upon the removal of CH<sub>3</sub>C(O)CH<sub>3</sub>, which may be affected by the additional loss of acetone due to the OH + acetone reaction where OH radicals are produced in the reaction of CH<sub>3</sub>CO with O<sub>2</sub>. However, the OH yield in the CH<sub>3</sub>CO + O<sub>2</sub> reaction is a strong function of pressure and measurements made at pressures >50 Torr are expected to have negligible errors.

The quantum yield data of Blitz et al.<sup>4,5</sup> are recommended. The optimized parameterization of the quantum yields for the wavelength range 279–327.5 nm, temperature range 218–295 K and pressure range 0–1000 mbar is as follows:

$$\Phi_{\text{TOTAL}}(\lambda, [\text{M}], T) = \Phi_{\text{CH}_3\text{CO}}(\lambda, [\text{M}], T) + \Phi_{\text{CO}}(\lambda, T); \quad \text{all } \lambda$$

**For  $\lambda = 279\text{-}327.5 \text{ nm}$**

$$\Phi_{\text{CO}}(\lambda, T) = 1 / (1 + A_0)$$

where

$$A_0 = [a_0 / (1 - a_0)] \exp[b_0 (\lambda - 248)]$$

$$a_0 = (0.350 \pm 0.003) (T/295)^{(-1.28 \pm 0.03)}$$

$$b_0 = (0.068 \pm 0.002) (T/295)^{(-2.65 \pm 0.20)}$$

**For  $\lambda = 279\text{-}302 \text{ nm}$**

$$\Phi_{\text{CH}_3\text{CO}}(\lambda, [\text{M}], T) = (1 - \Phi_{\text{CO}}(\lambda, T)) / (1 + A_1[\text{M}])$$

where

$$A_1 = a_1 \exp[-b_1 ((10^7/\lambda) - 33113)]$$

$$a_1 = (1.600 \pm 0.032) \times 10^{-19} (T/295)^{(-2.38 \pm 0.08)}$$

$$b_1 = (0.55 \pm 0.02) \times 10^{-3} (T/295)^{(-3.19 \pm 0.13)}$$

**For  $\lambda = 302\text{-}327.5 \text{ nm}$**

$$\Phi_{\text{CH}_3\text{CO}}(\lambda, [\text{M}], T) = ((1 + A_4[\text{M}] + A_3) / [(1 + A_2[\text{M}] + A_3)(1 + A_4[\text{M}])]) (1 - \Phi_{\text{CO}}(\lambda, T))$$

where

$$A_2 = a_2 \exp[-b_2 ((10^7/\lambda) - 30488)]$$

$$a_2 = (1.62 \pm 0.06) \times 10^{-17} (T/295)^{(-10.03 \pm 0.20)}$$

$$\begin{aligned}
b_2 &= (1.79 \pm 0.02) \times 10^{-3} (T/295)^{(-1.364 \pm 0.036)} \\
A_3 &= a_3 \exp[-b_3 ((10^7/\lambda) - c_3)^2] \\
a_3 &= (26.29 \pm 0.88) (T/295)^{(-6.59 \pm 0.23)} \\
b_3 &= (5.72 \pm 0.20) \times 10^{-7} (T/295)^{(-2.93 \pm 0.09)} \\
c_3 &= (30006 \pm 41) (T/295)^{(-0.064 \pm 0.004)} \\
A_4 &= a_4 \exp[-b_4 ((10^7/\lambda) - 30488)] \\
a_4 &= (1.67 \pm 0.14) \times 10^{-15} (T/295)^{(-7.25 \pm 0.54)} \\
b_4 &= (2.08 \pm 0.02) \times 10^{-3} (T/295)^{(-1.16 \pm 0.15)}
\end{aligned}$$

where [M] is in molecule cm<sup>-3</sup>,  $\lambda$  in nm and T in K. The equations given above have been used to calculate the quantum yields recommended in Table 4D-24.

It is well established that acetone photolysis at wavelengths >300 nm has a strong dependence on pressure and temperature but there remains some uncertainty in the absolute quantum yield values in this wavelength region. The effect of the temperature dependent quantum yields of acetone on the chemistry of the upper troposphere has been modeled by Arnold et al.<sup>2</sup> and shown to be significant. Additional quantum yield studies are desired at atmospherically relevant photolysis wavelengths, >290 nm, as a function of pressure and temperature to reduce uncertainties in model calculations.

## D22. CH<sub>3</sub>C(O)CH<sub>2</sub>OH (hydroxyacetone, acetol)

[Back to Index](#)

CH <sub>3</sub> C(O)CH <sub>2</sub> OH + hν	→ CH <sub>3</sub> C(O) + CH <sub>2</sub> OH	376 kJ mol <sup>-1</sup>	318 nm	(1)
	→ HOCH <sub>2</sub> C(O) + CH <sub>3</sub>	376 kJ mol <sup>-1</sup>	318 nm	(2)
	→ HOCH <sub>2</sub> + CO + CH <sub>3</sub>	335 kJ mol <sup>-1</sup>	357 nm	(3)
	→ HO + CH <sub>2</sub> C(O)CH <sub>3</sub>	335 kJ mol <sup>-1</sup>	357 nm	(4)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption cross sections of CH<sub>3</sub>C(O)CH<sub>2</sub>OH (hydroxyacetone, acetol) have been measured by Meller and Crowley<sup>5</sup> at 296 K in the range 207–333 nm; by Orlando et al.<sup>6</sup> at 298 K over the range 235–340 nm; and by Butkovskaya et al.<sup>2</sup> at 294 K over the range 240–350 nm using a static method, and at 328 K over the range 250–350 nm using a dynamic method. Dillon et al.<sup>4</sup> measured the cross section at 184.9 nm and 358 K to be  $(5.4 \pm 0.1) \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> whereas Baasandorj et al.<sup>1</sup> reported a value of  $(5.43 \pm 0.08) \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> at 298 K. The spectrum shows an absorption band with the maximum near 266 nm. The shape of the measured spectra are in excellent agreement except for the spectrum obtained by Butkovskaya et al.<sup>2</sup> using the dynamic method. The maxima cross sections reported by Butkovskaya et al.<sup>2</sup> are 15% and 24% lower for the static and dynamic methods, respectively, than the values obtained by Orlando et al.<sup>6</sup>; the maximum reported by Meller and Crowley<sup>5</sup> is 11% lower than that of Orlando et al.<sup>6</sup> Large discrepancies between the measured spectra exist at  $\lambda > 310$  nm.

In Table 4D-25 are listed the averages over 1 nm intervals of the cross sections of Orlando et al.<sup>6</sup> and Butkovskaya et al.<sup>2</sup> (static) in the wavelength range 240–310 nm; at 311–336 nm, only those of Orlando et al.<sup>6</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for removal of hydroxyacetone were estimated by Orlando et al.<sup>6</sup> to be  $0.65 \pm 0.25$  for the photolysis in the 240–420 nm band. They also suggested that  $0.3 \pm 0.2 < \Phi_1 + \Phi_2 < 0.6$  for wavelengths larger than 290 nm. Products detected were CO, CO<sub>2</sub>, CH<sub>2</sub>O, CH<sub>3</sub>COOH, CH<sub>3</sub>COO<sub>2</sub>H, HCOOH and CH<sub>3</sub>OH. These authors concluded that at most 50% of the photolysis occurred via channel (1). Direct observation of OH radicals, presumably arising from channel (4), was made by Chowdhury et al.<sup>3</sup> at 148 nm. Photolysis of hydroxyacetone at 193 nm was performed by Chowdhury et al.<sup>3</sup> and appears to occur by process (2) with the initial formation of HOCH<sub>2</sub>CO yielding OH and ketene.

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of glyoxal, CHOCHO, has been measured in a number of studies. The spectrum has two absorption bands in the wavelength region  $>220$  nm; a weak band with evidence of diffuse vibrational structure in the 220–350 nm region, and a stronger and highly structured band at wavelengths  $>360$  nm with a maximum near 455 nm. The absorption cross sections, particularly in the visible absorption band, are resolution dependent and comparison of results from the various studies need to take this into consideration. The room temperature absorption spectrum of glyoxal has been reported by Plum et al.<sup>11</sup> (230–460 nm), Langford and Moore<sup>6</sup> (308 nm), Zhu et al.<sup>15</sup> (193, 248, 308, and 351 nm), Chen and Zhu<sup>3</sup> (290–420 nm, in 10 nm intervals), Orlando and Tyndall<sup>9</sup> (210–450 nm, 0.6 nm resolution), Horowitz et al.<sup>5</sup> (210–480 nm, 0.25 nm resolution), Zhu and Johnston<sup>14</sup> (436–442 nm), and Volkamer et al.<sup>13</sup> (250–526 nm). Orlando and Tyndall<sup>9</sup> and Horowitz et al.<sup>5</sup> reported absorption spectra obtained using diode array spectroscopy and their spectra are in good agreement, i.e., to better than 10% between 240 and 440 nm. The absorption cross sections from Chen and Zhu<sup>3</sup> differ from these studies by 10 to 50% depending on the wavelength. However, the absorption cross sections reported by Zhu et al.<sup>15</sup> at 248, 308, and 351 nm agree very well with the data of Horowitz et al.<sup>5</sup> and Orlando and Tyndall.<sup>9</sup> A strong absorption feature at wavelengths  $<200$  nm indicated by the 193 nm measurement of Zhu et al.<sup>15</sup> ( $\sigma = 4.8 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ ) was also reported by Orlando and Tyndall.<sup>9</sup> The cross section data from Plum et al.<sup>11</sup> are systematically less, by roughly 10 to 25%, than reported in the more recent studies with larger differences in the region of the absorption minimum near 350 nm and at the shorter wavelengths.

Volkamer et al.<sup>13</sup> reported the highest available resolution absorption spectra of glyoxal to date which were obtained using Fourier transform spectroscopy at  $1 \text{ cm}^{-1}$  (250–526 nm) and  $0.06 \text{ cm}^{-1}$  (368–526 nm) resolution. The high-resolution spectrum has more pronounced differential vibrational fine structure in the visible absorption band leading to higher absorption cross sections than reported in the lower resolution studies. The absorption cross sections reported by Volkamer et al.<sup>13</sup> are systematically 10% greater than reported by Horowitz et al.<sup>5</sup> and Orlando and Tyndall<sup>9</sup> (where comparison is possible). The differences in the absorption cross sections are most apparent in the short wavelength band. The UV spectrum reported by Volkamer et al.<sup>13</sup> is consistent with IR spectral parameters which were obtained by simultaneous recording of UV and IR spectra using the same glyoxal sample fillings of the absorption cell. Zhu and Johnston<sup>14</sup> report an absorption cross section at the absorption maximum near 440.7 nm (440.1 nm in the Volkamer et al. spectrum) of  $4.6 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  that was obtained at high resolution using cavity ring-down spectroscopy. Their cross section value is in poor agreement with the high resolution data of Volkamer et al.<sup>13</sup> which is a factor of two greater. The recommended room temperature absorption cross sections in Table 4D-26 are averages over 1 nm intervals of the high resolution spectrum from Volkamer et al.<sup>13</sup> and are appropriate for use in atmospheric photolysis rate calculations. Studies requiring higher resolution data should consult the original literature.

*Photolysis Quantum Yield and Product Studies:* The photodissociation of CHOCHO as well as the photolysis product channel yields are wavelength and pressure dependent. Calvert and Pitts<sup>2</sup> have summarized the CHOCHO quantum yield data prior to 1966. On the basis of the work by Calvert and Layne<sup>1</sup> and Parmenter<sup>10</sup> it was established that the HCHO + CO photolysis channel (3) was dominant with yields between 0.84 and 0.6 over the wavelength range 254 to 435 nm. There was little experimental evidence for the HCO + HCO radical channel (1) occurring and it was incorrectly concluded to be negligible. Plum et al.<sup>11</sup> has since reported the effective quantum yield for CHOCHO photolysis at wavelengths  $>290$  nm to be 0.029, based on measured photolysis rates in an environmental chamber relative to NO<sub>2</sub> where  $J_{\text{CHOCHO}}/J_{\text{NO}_2}$  was found to be  $0.008 \pm 0.005$ . An effective atmospheric photolysis rate was measured using solar radiation in the EUPHORE outdoor chamber to be  $J_{\text{obs}} = 1.04 \pm 0.10 \times 10^{-4} \text{ s}^{-1}$ , corresponding to an effective quantum yield for glyoxal loss of  $0.035 \pm 0.007$ <sup>7,8</sup> in reasonable agreement with the value reported by Plum et al.<sup>11</sup>

Langford and Moore<sup>6</sup> measured HCO produced in the photolysis of glyoxal in 1000 Torr N<sub>2</sub> at 305 nm by direct HCO resonance absorption and deduced a total HCO yield of  $0.8 \pm 0.4$  at 305 nm. Using cavity ring-down spectroscopy, Zhu et al.<sup>15</sup> reported HCO quantum yields of 1.5 ( $\Phi_1 \approx 0.75$ ) for photolysis at 351 nm, 0.69 at 308 nm, 0.52 at 248 nm and 0.42 at 193 nm. In a later study Chen and Zhu<sup>3</sup> reported zero pressure

HCO yields,  $\Phi_0(\lambda)$ , at 10 nm intervals, that increase from  $0.50 \pm 0.01$  at 290 nm to a maximum of  $2.01 \pm 0.08$  at 390 nm and that decrease to  $0.74 \pm 0.08$  at 400 nm,  $0.56 \pm 0.04$  at 410 nm, and  $0.48 \pm 0.03$  at 420 nm. HCO quantum yields were found to be independent of the N<sub>2</sub> buffer gas pressure (10–400 Torr) for photolysis in the 290–370 nm region. In the wavelength region 380–420 nm the HCO quantum yield decreased with increasing pressure. They reported HCO quantum yields at 760 Torr N<sub>2</sub> to be 0.49 at 380 nm, 0.54 nm at 390 nm, 0.32 at 400 nm, 0.22 at 410 nm and 0.14 at 420 nm. Feierabend et al.<sup>4</sup> measured quantum yields for the production of HCO at 85 discrete wavelengths in the wavelength range 290–420 nm at pressures between 50 and 550 Torr (N<sub>2</sub>) at 298 K using pulsed laser photolysis combined with cavity ring-down spectroscopy detection of HCO.  $\Phi_0(\lambda)$  varied smoothly with wavelength with a maximum value of ~1.8 in the range 300–385 nm with values decreasing to near 0 at 420 nm and 0.4 at 290 nm. The high precision of the measurements enabled the pressure dependence of the HCO quantum yield to be determined at each wavelength using the Stern-Volmer relationship

$$\frac{1}{\Phi(\lambda, P)} = \frac{1}{\Phi_0(\lambda)} + \frac{k_q}{k_d}(\lambda)[N_2]$$

where  $k_q$  is the collisional quenching rate coefficient and  $k_d$  is the rate coefficient for the dissociation of glyoxal. The wavelength dependence of the rate coefficient ratio was fit to the expression

$$k_q/k_d(\lambda) = 2.3 \times 10^{-20} + 1.5 \times 10^{-19} \exp(-0.4 \Delta E) \quad (\text{cm}^3 \text{ molecule}^{-1})$$

where  $\Delta E = ((28571/\lambda) - 72.5)$  (kcal mol<sup>-1</sup>),  $\lambda$  is the photolysis wavelength (nm), and 72.5 kcal mol<sup>-1</sup> is the threshold for glyoxal photodissociation (there is a small barrier to dissociation on the triplet surface). The  $\Phi_0(\lambda)$  values from the Feierabend et al.<sup>4</sup> work are in good agreement with the values reported by Chen and Zhu.<sup>3</sup>

Tadić et al.<sup>12</sup> photolysed glyoxal with broadband fluorescent lamps, which selectively overlapped with the two absorption bands, and measured the CO, HCHO and HCOOH end products. Using 275–380 nm irradiation, the quantum yield for glyoxal loss was found to be  $\Phi_T = 0.97 \pm 0.05$  and independent of pressure. The absolute quantum yields obtained for 390–470 nm radiation, covering the visible absorption band, were found to be pressure dependent with values ranging from  $\Phi_T = 0.12$  at 100 Torr to  $\Phi_T = 0.04$  at 700 Torr and was described by the Stern-Volmer expression

$$\frac{1}{\Phi_T} = 6.80 + [251.8 \times 10^{-4} P(\text{Torr})]$$

The direct HCO quantum yield measurements of Feierabend et al.<sup>4</sup> and Chen and Zhu<sup>3</sup> combined with the end product yield results of Tadić et al.<sup>12</sup> indicate that dissociation into 2 HCO radicals is the most important pathway under atmospheric conditions. On the basis of their HCO quantum yield data, Feierabend et al. reported a set of revised wavelength dependent quantum yields for channels (1), (2) and (3) from those of Tadić et al.,<sup>12</sup> which were recommended in JPL 06-2. The revised quantum yields are recommended and given in Table 4D-27. Although glyoxal has a very low effective quantum yield, photolysis is an important removal path in the atmosphere.

#### D24. CH<sub>3</sub>C(O)C(O)H (methylglyoxal, MGLY)

[Back to Index](#)

CH <sub>3</sub> C(O)C(O)H + hν	→ CH <sub>3</sub> CO + HCO	305 kJ mol <sup>-1</sup>	422 nm	(1)
	→ CH <sub>4</sub> + 2CO	-25 kJ mol <sup>-1</sup>	All	(2)
	→ CH <sub>3</sub> CHO + CO	-6 kJ mol <sup>-1</sup>	All	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of methylglyoxal (MGLY), CH<sub>3</sub>C(O)C(O)H, has been measured at room temperature by Plum et al.<sup>5</sup> (230–470 nm), Meller et al.<sup>4</sup> (218–494 nm), Chen et al.<sup>1</sup> (290–440 nm), and Staffelbach et al.<sup>7</sup> (205–474 nm). The absorption spectrum exhibits two absorption bands, a slightly structured band between 225 and 335 nm and a stronger band between 335 and 475 nm, which is highly structured in the region above 410 nm. A steep increase of the absorption cross sections was observed at shorter wavelengths going from 225 to 200 nm by Staffelbach et al.<sup>7</sup>

The room temperature values of Meller et al.<sup>4</sup> and Staffelbach et al.<sup>7</sup> are in good agreement at wavelengths >230 nm. In the weaker absorption band the data of Meller et al.<sup>4</sup> are greater by up to 10–15%. In the strong absorption band up to 400 nm, the data of Staffelbach et al.<sup>7</sup> are greater by up to ~10% than the data of Meller et al.,<sup>4</sup> and at higher wavelengths the peak values reported by Meller et al.<sup>4</sup> are higher (due to the higher resolution used in their study) than those measured by Staffelbach et al.<sup>7</sup> The data points of Chen et al.<sup>1</sup> determined at 10 nm intervals fit well to the absorption curves of Meller et al.<sup>4</sup> and Staffelbach et al.<sup>7</sup> except at 380 and 400 nm where the differences are ~20%. The cross sections reported by Plum et al.<sup>5</sup> are approximately only the half of the cross sections reported Meller et al.<sup>4</sup> and Staffelbach et al.<sup>7</sup> The recommended absorption cross sections in Table 4D-28 are from Staffelbach et al.<sup>7</sup> in the region 200–218 nm, the mean of the values from Meller et al.<sup>4</sup> and Staffelbach et al.<sup>7</sup> in the region 219–235 nm, and averages over 1 nm intervals of the data from Meller et al.<sup>4</sup> in the region 236–493 nm.

The temperature dependence of the absorption spectrum is relatively weak with differences on the order of 10% observed in the spectra measured by Staffelbach et al.<sup>7</sup> at 298 and 248 K. The largest changes occur in the structured region between 410 and 450 nm where the fine structure becomes more pronounced at lower temperatures.

*Photolysis Quantum Yield and Product Studies:* Quantum yields have been measured in several studies. Kyle and Orchard<sup>3</sup> reported products formed in the photolysis of methylglyoxal at 387 K and 436 nm. Staffelbach et al.<sup>7</sup> measured the products after photolysis of dilute mixtures of methylglyoxal in air using a Xe arc equipped with different band pass filters to isolate several regions of the spectrum. The observed products (CO, CO<sub>2</sub>, HCHO, CH<sub>3</sub>COOH, CH<sub>3</sub>COOOH, CH<sub>3</sub>OH and HCOOH,) led to the conclusion that only channel (1) is important in the photolysis range 240–480 nm. Quantum yields were derived by modeling the products formed using a number of secondary radical reactions. At 760 Torr, the Φ<sub>1</sub> yields were: 0.005 for the wavelength region 410–418 nm, 0.055 for 355–480 nm, 0.07 for 280–240 nm and 0.14 for 240–420 nm.

Raber and Moortgat<sup>6</sup> irradiated methylglyoxal in air at different total pressures using two types of broadband lamps and determined the products (CO, CO<sub>2</sub>, HCHO, CH<sub>3</sub>OOH, CH<sub>3</sub>OH, HCOOH, CH<sub>3</sub>CHO, CH<sub>3</sub>COOH, CH<sub>3</sub>COOOH and CH<sub>3</sub>COCOOH). The quantum yield derived by modeling the products of the photolysis in the 275–380 nm region varied from 0.94 ± 0.04 at 54 Torr to 0.64 ± 0.03 at 760 Torr, and in the 390–470 nm region from 0.41 ± 0.04 to 0.23 ± 0.02.

Koch and Moortgat<sup>2</sup> determined the quantum yields of CO, HCHO and CH<sub>3</sub>CHO formation at 298 K as a function of wavelength (260–440 nm) and pressure of synthetic air (30–900 Torr) using “broad” monochromatic light, with an optical resolution of 8.5 nm. For photolysis in the 260–320 nm band, the overall quantum yield was found to be unity, independent of wavelength and pressure. The analysis of the data gave evidence that channel (1) is the predominant photolysis path. In the 380–440 nm band the quantum yield of CO showed a Stern-Volmer pressure dependence and the quantum yield of H<sub>2</sub>CO increased with increasing methylglyoxal pressure, which was attributed to the reaction of excited methylglyoxal with ground state methylglyoxal.

The quantum yield of channel (1) over the wavelength range 250–500 nm was expressed as

$$1/\Phi_1(\lambda) = 1/\Phi_0(\lambda) + P(\text{Torr}) / k(\lambda)$$

where

$$\Phi_0(\lambda) = 1 \text{ for } \lambda < 380 \text{ nm}$$

$$\Phi_0(\lambda) = (8.15 \pm 0.7) \times 10^{-9} [\exp(7131 \pm 267) / \lambda] \quad \text{for } \lambda > 380 \text{ nm}$$

$$k(\lambda) = (7.34 \pm 0.1) \times 10^{-9} [\exp(8793 \pm 300) / \lambda]$$

Chen et al.<sup>1</sup> used a tunable dye laser to photolysed methylglyoxal at 10 nm intervals over the range 290–440 nm combined with detection of the primary HCO radical photolysis product using cavity ring-down spectroscopy. The HCO quantum yield was calibrated against HCO produced in the photolysis of HCHO or Cl<sub>2</sub>/HCHO mixtures. They report the HCO quantum yield to be unity in the wavelength range 320–360 nm, 0.82 ± 0.06 at 290 nm, and to decrease at wavelengths >370 nm to a value of 0.17 ± 0.02 at 440 nm. The HCO quantum yields were reported to be independent of pressure between 290 and 370 nm for the pressure range 10–400 Torr N<sub>2</sub> but to have a Stern-Volmer pressure dependence at wavelengths ≥380 nm given by

$$1/\Phi_1(\lambda) = 1/\Phi_0(\lambda) + k_Q(\lambda) P(\text{Torr})$$

where

$$\Phi_0(\lambda) = (3.63 \pm 0.32) \times 10^{-7} [\exp(5693 \pm 533) / \lambda]$$

and

$$k_Q(\lambda) = (1.93 \pm 0.24) \times 10^4 [\exp(-(5639 \pm 497) / \lambda)]$$

The zero pressure quantum yields,  $\Phi_0(\lambda)$ , are in good agreement for wavelengths ≤ 420 nm. However, the quantum yields at 760 Torr from the Chen et al.<sup>1</sup> and Koch and Moortgat<sup>2</sup> expressions deviate by a factor 4 for wavelengths ≥ 420 nm. The data from the more direct study by Chen et al.<sup>1</sup> are recommended. Additional measurements are needed to establish the quantum yields in the long wavelength tail of the spectrum at atmospherically relevant pressures.

*Absorption Cross Sections:* The UV absorption spectrum of formic acid, HC(O)OH, and formic acid dimer, (HC(O)OH)<sub>2</sub>, have been measured near 300 K for a range of sample pressures by McMillan<sup>1</sup> (200–249 nm; 35.2, 16.4, and 2.45 Torr), Singleton et al.<sup>5</sup> (195–250 nm; 29 pressures between 0.5 and 22 Torr), Singleton et al.,<sup>7</sup> and Nagakura et al.<sup>4</sup> (154–191 nm). Jolly et al.<sup>3</sup> reported cross sections at 222 nm in connection with their quantum yield measurements. Singleton et al.<sup>7</sup> also measured spectra at 356.2 K. The absorption spectrum of the dimer has a broad maximum near 205 nm and a monotonic decrease in intensity with increasing wavelength. The absorption maximum of the monomer is shifted to longer wavelengths, with a peak cross section near 215 nm, about one third the magnitude of the peak cross section for the dimer. The decrease in cross sections with increasing wavelength is more rapid for the dimer than for the monomer, resulting in monomer cross sections being greater at 250 nm by approximately a factor 10. The absorption spectra reported by McMillan<sup>1</sup> were derived assuming monomers only in spite of undefined amounts of monomer and dimer contributions, resulting in a reported spectra that lies between those reported by Singleton et al.<sup>5</sup> for the monomer and the dimer. The recommended absorption cross sections in Table 4D-29 are taken from Singleton et al.<sup>5</sup> measured with a resolution of 1 nm.

*Photolysis Quantum Yield and Product Studies:* In the pre-1966 studies considered in Calvert and Pitts<sup>1</sup> yields of final products CO, CO<sub>2</sub>, H<sub>2</sub>, H<sub>2</sub>O (suggested as due to the molecular elimination channels 4 and 5) were determined. However, in the experiments considered it would be difficult to distinguish between primary photolytic products and products formed by subsequent secondary free-radical reactions. Jolly et al.<sup>3</sup> determined the quantum yield of OH formation at 222 nm for the monomer to be  $1.05 \pm 0.14$  and essentially zero for the dimer. In a follow-up study, Singleton et al.<sup>7</sup> re-determined the OH quantum yields at 222 nm to be  $0.704 \pm 0.048$  at 298 K and  $0.771 \pm 0.030$  at 356.2 K for the monomer, and  $0.153 \pm 0.028$  at 298 K for the dimer (the OH yield for the dimer at elevated temperatures was assumed to be zero). Photodissociation into the other radical channels, 2 and 3, is minor and has been discussed by He and Fang.<sup>2</sup> Photodissociation quantum yields for the dimer were determined at 222 nm by Singleton et al.<sup>6</sup> to be  $\Phi_{6,D} = 0.15$ ,  $\Phi_{7,D} = 0.81$  and  $\Phi_{8,D} = 0.04$ .

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of acetic acid, CH<sub>3</sub>C(O)OH, and the acetic acid dimer, (CH<sub>3</sub>C(O)OH)<sub>2</sub>, have been measured for a range of sample pressures at 300 K by McMillan<sup>1</sup> (200–241 nm; 12.9, 11.0, 8.3, and 3.6 Torr), at 283, 303 and 338 K by Hintze et al.<sup>2</sup> (195–220 nm), and at 270, 298, 325, and 345 K by Orlando and Tyndall<sup>4</sup> (210–245 nm; 0.12–3.6 Torr). Singleton et al.<sup>5</sup> reported cross sections at 222 nm in connection with quantum yield measurements at 298 and 356.2 K. The monomer spectrum reported by Orlando and Tyndall<sup>4</sup> and Hintze et al.<sup>2</sup> has a broad maximum near 207 nm and a monotonic decrease in intensity with increasing wavelength. The absorption maximum for the dimer appears at shorter wavelength, below 205 nm, and is twice as intense as that of the monomer. The decrease in cross sections with increasing wavelength is more rapid for the dimer than for the monomer resulting in the monomer cross section being greater at 240 nm by a factor 6. Hinze et al.<sup>2</sup> determined the absorption cross section at the maximum for the monomer at 206.1 nm and 297 K to be  $(1.27 \pm 0.10) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  and for the dimer and at 208.1 nm to be  $(2.44 \pm 0.08) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ . The absorption spectra reported by Calvert and Pitts<sup>1</sup> were derived assuming monomers only in spite of undefined amounts of monomer and dimer. The absorption spectrum for the greatest pressure is close to the dimer spectrum reported by Orlando and Tyndall<sup>4</sup>, suggesting that the sample was primarily dimer at the higher pressures. The recommended absorption cross sections in Table 4D-30 are taken from Orlando and Tyndall<sup>4</sup> (measured at 0.6 nm resolution).

*Photolysis Quantum Yield and Product Studies:* Early photolysis studies reported yields of the end products CO, CO<sub>2</sub>, CH<sub>4</sub>, and C<sub>2</sub>H<sub>6</sub> (Calvert and Pitts<sup>1</sup>) and proposed molecular elimination (channel 1) and radical formation (channels 2–4) originating from the monomer. Hunnicutt et al.<sup>3</sup> photolysed acetic acid at 218 nm and used photofragment laser fluorescence to determine channel (2) to be the dominant photochemical path. Singleton et al.<sup>5</sup> determined the OH quantum yield at 222 nm to be  $0.546 \pm 0.097$  at 298 K and  $0.692 \pm 0.024$  at 356.2 K for the monomer and  $0.038 \pm 0.026$  at 298 K for the dimer (a dimer quantum yield of zero was assumed at elevated temperatures).

## D27. CH<sub>3</sub>C(O)OOH (peracetic acid)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of peracetic acid, CH<sub>3</sub>C(O)OOH, was measured at 248 and 298 K by Orlando and Tyndall<sup>1</sup> (205–340 nm). The absorption cross sections decrease in a monotonic near-exponential fashion with increasing wavelength. The spectrum recorded at 248 K shows a faster fall-off with increasing wavelength than that recorded at room temperature. The recommended absorption cross sections in Table 4D-31 are taken from Orlando and Tyndall (the only study available) (measured at 0.6 nm resolution).

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**D28. C<sub>2</sub>H<sub>5</sub>C(O)OH (propionic acid)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of propionic acid, C<sub>2</sub>H<sub>5</sub>C(O)OH, and the propionic acid dimer, (C<sub>2</sub>H<sub>5</sub>C(O)OH)<sub>2</sub>, have been measured by Hinze et al.<sup>1</sup> (195–220 nm) at 283, 303 and 338 K and Vicente et al.<sup>3</sup> (115–257 nm) at 313 K. The spectrum has a strong absorption band in the region 115–192 nm and a weaker band in the region 192–248 nm with a broad maximum near 207 nm. Hinze et al.<sup>1</sup> determined the absorption cross section for the monomer at 206.1 nm and 297 K to be  $(1.52 \pm 0.16) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ . The dimer cross section at 208.1 nm was determined to be  $(3.24 \pm 0.22) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ . Absorption cross sections have also been measured at 298 and 356.2 K and 222 nm by Singleton et al.<sup>2</sup> These investigators obtained absorption cross sections of  $12.2 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  at 298 K and  $10.6 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  at 356.2 K for the monomer and derived absorption cross sections of  $10.6 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  at 298 K and  $25.6 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  at 356.2 K for the dimer by an extrapolation procedure.

*Photolysis Quantum Yield and Product Studies:* Quantum yields for the formation of OH radicals at 222 nm have been measured by Singleton et al.<sup>2</sup> to be  $0.148 \pm 0.90$  and  $0.341 \pm 0.014$  for the monomer at 297.6 and 375.0 K, respectively, and  $0.018 \pm 0.06$  at 297.6 K for the dimer (an OH quantum yield of zero for the dimer was assumed at elevated temperatures).

**D29. CH<sub>3</sub>C(O)C(O)OH (pyruvic acid)**[Back to Index](#)

(1)

(2)

(3)

(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of pyruvic acid, CH<sub>3</sub>C(O)C(O)OH, has been measured at room temperature by Horowitz et al.<sup>2</sup> (250–410 nm, 0.25 nm resolution) and Mellouki and Mu<sup>3</sup> (290–380 nm). An absorption spectrum of pyruvic acid has also been reported by Yamamoto and Back<sup>7</sup> (250–400 nm) at 358 K. The continuous absorption band between 275–400 nm peaks near 350 nm and contains significant diffuse vibrational band structure. Absolute cross sections for the relative spectrum reported by Yamamoto and Back<sup>7</sup> were given in Horowitz et al.<sup>2</sup> following normalization of the spectrum at 350 nm to  $3.82 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ . The general shapes of the reported spectra are qualitatively similar although the spectrum reported by Yamamoto and Back<sup>7</sup> is red shifted and the cross sections at wavelengths <300 nm are considerably greater. This difference in cross section may in part be ascribed to the effect of temperature on the spectrum. The cross sections measured by Mellouki and Mu<sup>3</sup> are systematically greater than those obtained by Horowitz et al.<sup>2</sup> The difference reaches a factor of two for wavelengths <295 nm and is ~20–30% between 305 and 370 nm. These differences are most likely due to the difficulties in handling the pyruvic acid sample and determining its concentration. The recommended absorption cross sections in Table 4D-32 are 1 nm averages from Horowitz et al.<sup>2</sup> in the range 252–285 nm, the mean of the data from Horowitz et al.<sup>2</sup> and Mellouki and Mu<sup>3</sup> (both 1 nm averages) in the range 290–380 nm, and the data from Horowitz et al.<sup>2</sup> in the range 385–399 nm.

*Photolysis Quantum Yield and Product Studies:* Moortgat<sup>4</sup> reported an effective quantum yield for pyruvic acid photodissociation under atmospheric conditions from a study in an outdoor photoreactor to be  $0.43 \pm 0.07$ . Vesley and Leermakers<sup>5</sup> reported quantum yields of CO<sub>2</sub> of  $1.02 \pm 0.06$  and of CH<sub>3</sub>CHO of 0.6 for photolysis at 366 nm. Yamamoto and Back<sup>7</sup> measured quantum yields of CO<sub>2</sub> of  $0.9 \pm 0.1$  and CH<sub>3</sub>CHO of 0.45 at 366 nm and 340 K. The CH<sub>3</sub>CHO yields obtained for 320 and 345 nm photolysis were more variable.

Berges and Warneck<sup>1</sup> measured the quantum yields of CH<sub>3</sub>CHO, CO<sub>2</sub> and CH<sub>3</sub>COOH at 350 nm to be 0.48 ± 0.01, 1.27 ± 0.18 and 0.14, respectively. In the presence of NO<sub>2</sub>, the quantum yield of CH<sub>3</sub>CHO was reduced to 0.30 ± 0.04 and PAN was formed with a quantum yield of 0.15 ± 0.02. Berges and Warneck<sup>1</sup> established  $\Phi_1 = 0.48 \pm 0.01$  and  $\Phi_2 = 0.39 \pm 0.10$ . Mellouki and Mu<sup>3</sup> used a laser flash photolysis system at 355 nm and observed the formation of OH originating via channel (4) with a quantum yield of  $\Phi_4 = 0.05 \pm 0.03$ . The analysis of the products CH<sub>3</sub>CHO, CO, CH<sub>3</sub>COOH by Winterhalter et al.<sup>6</sup> are consistent with the data of Berges and Warneck<sup>1</sup> and lead to a quantum yield of channel (3)  $\Phi_3 = 0.08 \pm 0.03$ . For the photolysis of pyruvic acid at 366 nm the following quantum yields are recommended  $\Phi_1 = 0.48 \pm 0.01$ ,  $\Phi_2 = 0.39 \pm 0.10$ ,  $\Phi_3 = 0.08 \pm 0.03$  and  $\Phi_4 = 0.05 \pm 0.03$ .

### D30. HC(O)OCH<sub>3</sub> (methyl formate)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of methyl formate, HC(O)OCH<sub>3</sub>, has been measured at room temperature by McMillan<sup>1</sup> (201–260 nm) and Vésine and Mellouki<sup>2</sup> (211–260 nm). The spectrum consists of a continuous absorption band with a maximum near 215 nm and weak diffuse structure. There is good agreement, better than 10%, among the results from these studies. The recommended cross sections in Table 4D-33 are taken from McMillan<sup>1</sup> for the region 202–210 nm (read from a figure) and Vésine and Mellouki<sup>2</sup> for the region 211–260 nm. The Vésine and Mellouki<sup>2</sup> data given here are averages of their high resolution (0.04 nm) spectrum over 1 and 2 nm intervals in the ranges 211–230 and 230–260 nm, respectively.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4D-33. Recommended Absorption Cross Sections of HC(O)OCH<sub>3</sub> at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

### D31. HC(O)OC<sub>2</sub>H<sub>5</sub> (ethyl formate)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of ethyl formate, HC(O)OC<sub>2</sub>H<sub>5</sub>, has been measured at room temperature by McMillan<sup>1</sup> (201–260 nm) and Vésine and Mellouki<sup>2</sup> (211–260 nm). The spectrum exhibits a structured absorption band with the maximum near 215 nm. The two data sets agree within ~15% with the data of Vésine and Mellouki<sup>2</sup> being systematically smaller. An explanation for the discrepancy could not be found by Vésine and Mellouki.<sup>2</sup> The recommended absorption cross sections in Table 4D-34 are the high resolution (0.04 nm) data of Vésine and Mellouki<sup>2</sup> averaged over 1 and 2 nm intervals in the ranges 211–230 and 230–260 nm, respectively.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4D-34. Recommended Absorption Cross Sections of HC(O)OC<sub>2</sub>H<sub>5</sub> at 297 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )						
211	18.6	220	17.8	229	11.2	246	1.47
212	18.6	221	17.1	230	11.0	248	1.04
213	18.3	222	15.9	232	9.03	250	0.665
214	18.5	223	15.1	234	7.21	252	0.405
215	19.0	224	15.0	236	6.50	254	0.251
216	18.9	225	14.9	238	4.96	256	0.119
217	18.1	226	14.0	240	3.67	258	0.0611
218	17.5	227	12.6	242	3.00	260	0.0391
219	17.6	228	11.5	244	2.18		

Note:

Vésine and Mellouki,<sup>2</sup> averaged over 1 and 2 nm intervals

**D32. HCN (hydrogen cyanide)**[Back to Index](#)

(Recommendation: 82-57, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Herzberg and Innes<sup>1</sup> have studied the spectroscopy of hydrogen cyanide, HCN, that starts absorbing weakly at  $\lambda < 190$  nm.

*Photolysis Quantum Yield and Product Studies:* The solar photodissociation rate for HCN is small, even in the upper stratosphere. Estimates of the HCN atmospheric photolysis rate require additional studies of the absorption cross sections and quantum yields in the 200 nm region.

No recommendations for either the absorption cross sections or quantum yields are provided.

**D33. CH<sub>3</sub>CN (methyl cyanide)**[Back to Index](#)

(Recommendation: 82-57, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Acetonitrile (CH<sub>3</sub>CN, methyl cyanide) absorbs weakly at wavelengths  $> 180$  nm with absorption cross sections  $< 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup>. Suto and Lee<sup>3</sup> (114–178 nm), Zetzsch<sup>4</sup> (155–185 nm), and Eden et al.<sup>1</sup> (113–320 nm) have reported cross section data. The agreement among the cross section data sets is, however, poor and no cross section recommendation is given.

*Photolysis Quantum Yield and Product Studies:* McElcheran et al.<sup>2</sup> studied the photodissociation of CH<sub>3</sub>CN at 184.9 nm. On the basis of end-product analysis, channel (1) was identified as the major photolysis pathway.

## SECTION 4E. FO<sub>x</sub> PHOTOCHEMISTRY

### E1. HF (hydrogen fluoride)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10 Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of hydrogen fluoride, HF, has been measured at 289.5, 326, 373, and 438 K by Safary et al.<sup>5</sup> and Safary<sup>4</sup> (153–182 nm) and at room temperature by Nee et al.<sup>3</sup> (107–145 nm), Carnovale et al.<sup>1</sup> (8–155 nm), and Hitchcock et al.<sup>2</sup> (30–200 nm). HF does not absorb significantly at wavelengths >180 nm. On the basis of the Nee et al. VUV spectrum, a Lyman- $\alpha$  (121.567 nm) cross section of  $3.1 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  is recommended.

*Photolysis Quantum Yield and Product Studies:* Photodissociation should be an unimportant loss process in the stratosphere.

### E2. FO<sub>2</sub> (fluoroperoxy radical)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The gas-phase UV absorption spectrum of the fluoroperoxy radical, FO<sub>2</sub>, has been measured at room temperature by Pagsberg et al.<sup>6</sup> (206–250 nm; reported in Wayne et al.<sup>7</sup>), Maricq and Szente<sup>4</sup> (186–276 nm), Ellermann et al.<sup>2</sup> (215–254 nm), and at 215 nm by Lyman and Holland.<sup>3</sup> In earlier studies, Chegodaev and Tupikov<sup>1</sup> and Matchuk et al.<sup>5</sup> reported spectra of FO<sub>2</sub> in liquid argon at 87 K. The results from Maricq and Szente,<sup>4</sup> Ellermann et al.,<sup>2</sup> and Lyman and Holland<sup>3</sup> are in excellent agreement. The cross sections measured by Pagsberg et al.<sup>6</sup> are larger by factors of 1.4 to 1.8 between 206 and 245 nm and a factor of 3 at 250 nm. The recommended absorption cross sections in Table 4E-1 are taken from Maricq and Szente.<sup>4</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

### E3. F<sub>2</sub>O (difluorine monoxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of difluorine monoxide, F<sub>2</sub>O, has been measured at 273 K over the wavelength range 210–546 nm by Glissmann and Schuhmacher,<sup>1</sup> the only study available. Their absorption cross section data are recommended and are listed in Table 4E-2.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

### E4. F<sub>2</sub>O<sub>2</sub> (dioxygen difluoride)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The gas-phase UV/vis absorption spectrum of dioxygen difluoride, F<sub>2</sub>O<sub>2</sub>, has been measured at 193 K by Chegodaev and Tupikov<sup>2</sup> (197–260 nm), at 195 K by Matchuk et al.<sup>5</sup> (350–600 nm), at 273 K by Brodersen et al.<sup>1</sup> (220–522.5 nm), and at 298 K by Lyman and Holland<sup>4</sup> (215 nm). A measurement of F<sub>2</sub>O<sub>2</sub> in liquid freon at 77 K has been reported by Kirshenbaum and Streng<sup>3</sup> (200–480 nm). The absorption spectrum shows decreasing absorption cross sections with increasing wavelength and evidence for several transitions that appear as shoulders in the spectrum. An absorption feature near 405 nm

reported by Brodersen et al.<sup>1</sup> does not appear in the spectra reported by Matchuk et al.<sup>5</sup> and Kirshenbaum and Streng.<sup>3</sup> Although measured at significantly different temperatures, the data from Brodersen et al.<sup>1</sup> and Chegodaev and Tupikov<sup>2</sup> in the wavelength range 220–250 nm agree to within 10-15%, with the Chegodaev and Tupikov data being systematically lower. The recommended absorption cross sections in Table 4E-3 are from Chegodaev and Tupikov<sup>2</sup> in the region 200–210 nm, Brodersen et al.<sup>1</sup> in the region 220–360 nm, and Matchuk et al.<sup>5</sup> for the 370–600 nm region.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## E5. FNO (nitrosyl fluoride)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of nitrosyl fluoride, FNO, has been measured at room temperature by Burley et al.<sup>1</sup> (180–350 nm) and Pagsberg et al.<sup>3</sup> (310.5 nm). Johnston and Bertin<sup>2</sup> report a cross section at 195 K and 310.5 nm. The FNO spectrum has two similar strength bands centered at 180 nm and 310 nm. The 310 nm band has significant vibronic structure at wavelengths >250 nm. The agreement between the single wavelength measurement of Pagsberg et al.<sup>3</sup> and the Burley et al.<sup>1</sup> spectrum is good. The recommended absorption cross sections in Table 4E-4 are at 2 nm intervals for the continuous region of the spectrum ( $\lambda < 260$  nm) and at 1 nm intervals in the structured region ( $\lambda > 260$  nm).

*Photolysis Quantum Yield and Product Studies:* The quantum yield for decomposition is expected to be unity.

**Table 4E-4. Recommended Absorption Cross Sections of FNO at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )						
180	52.4	246	1.65	286	5.17	319	21.4

**E6. CHF<sub>3</sub> (trifluoromethane, HFC-23)**[Back to Index](#)

(1)

(New Entry)

*Absorption Cross Sections:* Trifluoromethane, CHF<sub>3</sub> (HFC-23), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-23 was measured at 298 K by Sauvageau et al.<sup>1</sup> (62–122 nm) and Suto and Lee<sup>2</sup> (106–124 nm). The two studies differ by ~50% at Lyman-α (121.567 nm). The recommended Lyman-α cross section is an average of the results from these two studies,  $3.5 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup>, where the Sauvageau et al. data were linearly interpolated to 121.567 nm. An uncertainty factor of 2 (2σ) is assigned, which encompasses the results from both studies.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E7. CH<sub>2</sub>F<sub>2</sub> (difluoromethane, HFC-32)**

[Back to Index](#)

(1)

(New Entry)

*Absorption Cross Sections:* Difluoromethane, CH<sub>2</sub>F<sub>2</sub> (HFC-32), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-32 at 298 K was measured by Sauvageau et al.<sup>1</sup> (60–142 nm; reported in 0.1 to 0.5 nm intervals) and Seccombe et al.<sup>2</sup> (60–152 nm; reported in ~0.015 nm intervals). The cross sections reported in these studies agree at Lyman- $\alpha$  (121.567 nm) to within ~30%. An average Lyman- $\alpha$  cross section from these studies,  $5.5 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ , is recommended. An uncertainty factor of 1.4 (2 $\sigma$ ) is recommended, which covers the range of experimental data.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Sauvageau, P.; Gilbert, R.; Berlow, P. P.; Sandorfy, C. Vacuum ultraviolet absorption spectra of fluoromethanes. *J. Chem. Phys.* **1973**, *59*, 762-765.

Vacuum-ultraviolet absorption and fluorescence spectroscopy of CF<sub>2</sub>H<sub>2</sub>, CF<sub>2</sub>Cl<sub>2</sub>, and CF<sub>2</sub>Br<sub>2</sub> in the range 8–22 eV. *J. Chem. Phys.* **2001**, *114*, 4058-4073, doi:10.1063/1.1344888.

**E8. CHF<sub>2</sub>CF<sub>3</sub> (pentafluoroethane, HFC-125)**

[Back to Index](#)

(1)

(New Entry)

*Absorption Cross Sections:* Pentafluoroethane, CHF<sub>2</sub>CF<sub>3</sub> (HFC-125), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-125 has not been reported to date. The recommended Lyman- $\alpha$  cross section of HFC-125 is assumed to be similar to that of CHF<sub>3</sub> (HFC-23) with an estimated value of  $3.5 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ . An uncertainty factor of 3.0 (2 $\sigma$ ) is assigned due to the lack of experimental data.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E9. CH<sub>2</sub>FCF<sub>3</sub> (1,1,1,2-tetrafluoroethane, HFC-134a)**

[Back to Index](#)

(1)

(New Entry)

*Absorption Cross Sections:* 1,1,1,2-tetrafluoroethane, CH<sub>2</sub>FCF<sub>3</sub> (HFC-134a), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-134a has not been reported to date. The Lyman- $\alpha$  cross section of HFC-134a is expected to be less than that of CH<sub>3</sub>CF<sub>3</sub> (HFC-143a) and comparable to that of CH<sub>2</sub>F<sub>2</sub> (HFC-32). An estimated value of  $5 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  is recommended. An uncertainty factor of 2.0 (2 $\sigma$ ) is assigned based on the lack of experimental data.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E10. CH<sub>3</sub>CF<sub>3</sub> (1,1,1-trifluoroethane, HFC-143a)**

[Back to Index](#)

(1)

(New Entry)

*Absorption Cross Sections:* 1,1,1-trifluoroethane, CH<sub>3</sub>CF<sub>3</sub> (HFC-143a), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-143a was measured by Sauvageau et al.<sup>1</sup> between 61 and 132 nm at 298 K with a Lyman- $\alpha$  cross section of  $1.75 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ , which is

recommended. The uncertainty factor for the Lyman- $\alpha$  cross section is assigned a value of 2.0 ( $2\sigma$ ) based primarily on the limited available data.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Sauvageau, P.; Doucet, J.; Gilbert, R.; Sandorfy, C. Vacuum ultraviolet and photoelectron spectra of fluoroethanes. *J. Chem. Phys.* **1974**, *61*, 391–395.

## E11. CH<sub>3</sub>CHF<sub>2</sub> (1,1-difluoroethane, HFC-152a)

[Back to Index](#)

(1)

(New Entry)

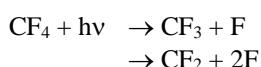

*Absorption Cross Sections:* 1,1-difluoroethane, CH<sub>3</sub>CHF<sub>2</sub> (HFC-152a), has negligible absorption at wavelengths  $>190$  nm. The VUV absorption spectrum of HFC-152a was measured by Sauvageau et al.<sup>1</sup> between 60 and 134 nm at 298 K with a Lyman- $\alpha$  cross section of  $3.2 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ , which is recommended. The uncertainty factor for the Lyman- $\alpha$  cross section is assigned a value of 2.0 ( $2\sigma$ ) based primarily on the limited available data.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Sauvageau, P.; Doucet, J.; Gilbert, R.; Sandorfy, C. Vacuum ultraviolet and photoelectron spectra of fluoroethanes. *J. Chem. Phys.* **1974**, *61*, 391–395.

## E12. CF<sub>4</sub> (carbon tetrafluoride)

[Back to Index](#)

507 kJ mol<sup>-1</sup>      236.1 nm      (1)  
1030 kJ mol<sup>-1</sup>      116.1 nm      (2)

(Recommendation: 90-1, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV spectrum of carbon tetrafluoride, CF<sub>4</sub>, consists of a strong absorption band between 6 and 120 nm with several broad features assigned to a Rydberg series with maxima near 54, 68, 78, 90 and 99 nm. The spectrum also has discrete vibrational structure in the region 56 to 63 nm. The absolute absorption cross sections have been studied extensively in the VUV by a number of groups as summarized in Table 4E-5. General agreement (to within a factor of 2) exists in the wavelength range 6–100 nm among the data of Rebbert and Ausloos,<sup>10</sup> Sauvageau et al.,<sup>11</sup> Lee et al.,<sup>7</sup> Cole and Dexter,<sup>3</sup> Lee et al.,<sup>8</sup> Au et al.,<sup>1</sup> Cook and Ching,<sup>4</sup> Hatherly and Flaxman,<sup>5</sup> and Chim et al.<sup>2</sup>

The absorption cross section at Lyman- $\alpha$  (121.567 nm) was reported to be  $(5.73 \pm 0.97) \times 10^{-21} \text{ cm}^2 \text{ molecule}^{-1}$  by Inn,<sup>6</sup>  $<1 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  by Lee et al.,<sup>8</sup> and  $<8 \times 10^{-22} \text{ cm}^2 \text{ molecule}^{-1}$  by Ravishankara et al.<sup>9</sup> A value of  $5.5 \times 10^{-21} \text{ cm}^2 \text{ molecule}^{-1}$  with an uncertainty factor of 2 ( $2\sigma$ ) is recommended for the cross section at Lyman- $\alpha$ .

*Photolysis Quantum Yield and Product Studies:* No recommendation. CF<sub>4</sub> does not absorb strongly at wavelengths  $>120$  nm and therefore it is not expected to photodissociate until it reaches the mesosphere.

**Table 4E-5. Summary of CF<sub>4</sub> Absorption Cross Section Studies**

### E13. $\text{C}_2\text{F}_6$ (hexafluoroethane)

[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV absorption spectrum of hexafluoroethane,  $\text{C}_2\text{F}_6$ , consists of a strong absorption band between 6 and 120 nm with several broad features and maxima near 58, 68, 79, 87 and 93 nm. Absolute absorption cross sections have been reported by Sauvageau et al.<sup>4</sup> (60–117 nm), Lee et al.<sup>2</sup> (18–74 nm), and Cole and Dexter<sup>1</sup> (6.5–10.0 nm). The cross section data from Sauvageau et al. over the range 60 to 75 nm are much smaller than those of Lee et al.

The absorption cross section at Lyman- $\alpha$  (121.567 nm) was determined by Ravishankara et al.<sup>3</sup> to be  $(9.87 \pm 0.35) \times 10^{-21} \text{ cm}^2 \text{ molecule}^{-1}$ , which is recommended.

*Photolysis Quantum Yield and Product Studies:* No recommendation.  $\text{C}_2\text{F}_6$  does not absorb significantly at wavelengths >120 nm and therefore it is not expected to photodissociate until it reaches the mesosphere.

- (1) Cole, B. E.; Dexter, R. N. Photoabsorption cross sections for chlorinated methanes and ethanes between 46 and 100 Å. *J. Quant. Spectrosc. Radiat. Transfer* **1978**, *19*, 303-309.

### E14. *c*- $\text{C}_4\text{F}_8$ (perfluorocyclobutane)

[Back to Index](#)

(1)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The spectrum of perfluorocyclobutane, *c*- $\text{C}_4\text{F}_8$ , consists of a strong absorption band in the VUV with a maximum at 117 nm and shows further weak absorption bands at 137 and 174 nm up to about 200 nm. The absolute photoabsorption cross sections have been measured at high resolution in the VUV by Limão-Vieira et al.<sup>1</sup> in the range 115–204 nm, although the data in the wavelength range >190 nm is

scattered. They estimated a stratospheric photolysis lifetime of ~400 years at 20 km decreasing to a few days at 40–50 km.

The absorption cross section at Lyman- $\alpha$  (121.567 nm) was determined by Limão-Vieira et al.<sup>1</sup> to be  $7.98 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  and Ravishankara et al.<sup>2</sup> reported a value of  $(8.76 \pm 0.49) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ . An average of the Lyman- $\alpha$  cross sections from these studies is recommended,  $8.37 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  with a 1.05 uncertainty factor ( $2\sigma$ ), which encompasses the results from both studies.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### E15. C<sub>5</sub>F<sub>12</sub> (perfluoropentane)

[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* No absorption spectrum of perfluoropentane, C<sub>5</sub>F<sub>12</sub>, is known. An absorption cross section at Lyman- $\alpha$  (121.567 nm) was determined by Ravishankara et al.<sup>1</sup> to be  $(5.32 \pm 0.30) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ , which is recommended.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

#### E16. C<sub>6</sub>F<sub>14</sub> (perfluorohexane)

[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections.* No absorption spectrum of C<sub>6</sub>F<sub>14</sub>, perfluorohexane, is known. An absorption cross section at Lyman- $\alpha$  (121.567 nm) was determined by Ravishankara et al.<sup>1</sup> to be  $(9.82 \pm 0.53) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ , which is recommended.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

#### E17. (CF<sub>3</sub>)<sub>2</sub>c-C<sub>4</sub>F<sub>6</sub> (perfluoro-1,2-dimethylcyclobutane)

[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* No absorption spectrum of perfluoro-1,2-dimethylcyclobutane, (CF<sub>3</sub>)<sub>2</sub>c-C<sub>4</sub>F<sub>6</sub>, is known. An absorption cross section at Lyman- $\alpha$  (121.567 nm) was determined by Ravishankara et al.<sup>1</sup> to be  $(1.22 \pm 0.07) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ , which is recommended. The large cross section implies a local lifetime of only a few days in the mesosphere.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

**E18. COF<sub>2</sub> (carbonyl difluoride)**[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of carbonyl difluoride (difluorophosgene), COF<sub>2</sub>, has been measured at room temperature by Chou et al.<sup>1</sup> (185–226 nm), Molina and Molina<sup>2</sup> (186–224 nm), and Nölle et al.<sup>3</sup> (199–232 nm). The high resolution spectrum reported by Nölle et al.<sup>3</sup> is highly structured. The cross section data from Nölle et al.<sup>3</sup> are somewhat larger than those from Molina and Molina<sup>2</sup> with differences in the averaged values over 500 cm<sup>-1</sup> intervals ranging between 1.5 and 22%. The cross section data of Chou et al.<sup>1</sup> are in good agreement with the data from Molina and Molina<sup>2</sup> in the region 186–197 nm. At longer wavelengths the cross sections from these studies diverge with the Chou et al. results being larger, ~200% near 225 nm. The recommended absorption cross sections in Table 4E-6 are the 500 cm<sup>-1</sup> averages of the data from Molina and Molina<sup>2</sup> in the range 186–199 nm and the data from Nölle et al.<sup>3</sup> at longer wavelengths. The recommended uncertainty factor in the room temperature spectrum is 1.30 (2σ) for all wavelengths included in Table 4E-6.

*Photolysis Quantum Yield and Product Studies:* The photodissociation of COF<sub>2</sub> has been studied by Nölle et al.<sup>4</sup> at 193, 210, and 220 nm and Molina and Molina<sup>2</sup> at 206 nm. Nölle et al.<sup>4</sup> determined the COF + F quantum yields by combining FTIR detection of products with excimer laser photolysis at 193 nm and Hg lamp photolysis at 210 and 220 nm. The “apparent” quantum yields for COF<sub>2</sub> were 0.47 ± 0.03, 0.57 ± 0.05, and 0.11 ± 0.02 at 193, 210 and 220 nm, respectively. In the case of the laser photolysis at 193 nm, where high concentrations of COF are formed, the self-reaction of the COF photodissociation product regenerates COF<sub>2</sub> via COF + COF → COF<sub>2</sub> + CO. Assuming that all COF radicals react quantitatively in this way, the actual quantum yield at 193 nm is 0.94 ± 0.06. The quantum yields at 210 and 220 nm obtained using the Hg lamp photolysis generated much lower COF radical concentrations and are reported as the actual quantum yields. Molina and Molina<sup>2</sup> report a quantum yield of 0.26 at 206 nm that is considerably lower than reported by Nölle et al.<sup>4</sup> On the basis of the Nölle et al. study a COF<sub>2</sub> photolysis quantum yield of unity is recommended for wavelengths less than 210 nm.

**E19. COHF (formyl fluoride)**[Back to Index](#)

COHF + hν	→ HF + CO	-27 kJ mol <sup>-1</sup>	All	(1)
	→ H + FCO	425 kJ mol <sup>-1</sup>	282 nm	(2)
	→ F + HCO	504 kJ mol <sup>-1</sup>	237.2 nm	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of formyl fluoride, COHF, has been measured at room temperature by Giddings and Innes<sup>1</sup> (195–255 nm), Meller (194–267 nm) (see Röth et al.<sup>3</sup>), and Rattigan et al.<sup>2</sup> (220–267 nm). The high-resolution measurements show the long-wavelength wing of a highly structured absorption band. The absorption cross sections reported by Giddings and Innes<sup>1</sup> are larger by nearly a factor of two than the high resolution (0.016 nm) data reported by Meller using diode array spectrometry. The cross sections measured by Rattigan et al.<sup>2</sup> at a resolution of 1.2 nm lie between the Giddings and Innes<sup>1</sup> and Meller data sets in the range 220–230 nm and are closer to the data of Giddings and Innes<sup>1</sup> in the region 230–245 nm. Rattigan et al.<sup>2</sup> found the absorption cross sections to be independent of temperature over the range 233–318 K. The recommended absorption cross sections in Table 4E-7 are averages over 1 nm intervals of the high-resolution data from Meller.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E20. CF<sub>3</sub>O<sub>2</sub> (trifluoromethylperoxy radical)**[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption cross sections of the trifluoromethylperoxy radical, CF<sub>3</sub>O<sub>2</sub>, have been measured at room temperature by Maricq and Szente<sup>1</sup> (186–276 nm) and Nielsen et al.<sup>2</sup> (215–270 nm). The absorption spectrum displays a broad absorption band with a maximum at 210 nm. The cross sections reported by Nielsen et al.<sup>2</sup> are in good agreement with those measured by Maricq and Szente<sup>1</sup> in the range 240–270 nm, but are consistently smaller at shorter wavelengths (by 20% at 215 nm). The recommended absorption cross sections listed in Table 4E-8 are taken from Maricq and Szente.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

Photolysis of CF<sub>3</sub>O<sub>2</sub>CF<sub>3</sub> in the presence of O<sub>3</sub> in oxygen: kinetic study of the reactions of CF<sub>3</sub>O and CF<sub>3</sub>O<sub>2</sub> radicals with O<sub>3</sub>. *J. Photochem. Photobio. A: Chem.* **1995**, 86, 15–25.

**E24. CF<sub>3</sub>CHO (trifluoroacetaldehyde)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of trifluoroacetaldehyde, CF<sub>3</sub>CHO, has been measured at room temperature by Lucazeau and Sandorfy<sup>6</sup> (118–182 and 250–357 nm), Meller et al.<sup>7</sup> (229–364 nm), Francisco and Williams<sup>4</sup> (230–400 nm), Sellevåg et al.<sup>10</sup> (200–400 nm), Hashikawa et al.<sup>5</sup> (200–500 nm), and Chiappero et al.<sup>2</sup> (230–360 nm). The UV absorption spectrum has an absorption band between 227 and 360 nm with a maximum at 301 nm and weak diffuse structure at wavelengths >250 nm. The absorption cross sections reported by Francisco and Williams,<sup>4</sup> Meller et al.,<sup>7</sup> Sellevåg et al.,<sup>10</sup> Hashikawa et al.,<sup>5</sup> and Chiappero et al.<sup>2</sup> are in reasonable agreement, generally to within 10% or better, in the wavelength region 245–354 nm. There are larger discrepancies in the long and short wavelength wings of the absorption band. In these regions, the cross sections from Sellevåg et al.<sup>10</sup> are smaller than those from Francisco and Williams<sup>4</sup> and larger than those from Meller et al.<sup>7</sup> The data of Lucazeau and Sandorfy,<sup>6</sup> which are reported in graphical form, are appreciably smaller than those reported in the other studies. The recommended absorption cross sections in Table 4E-11 are taken from Sellevåg et al.<sup>10</sup>

The temperature dependence of the absorption spectrum was examined by Chiappero et al.<sup>2</sup> (230–360 nm) between 249 and 297 K. No discernible variation of the absorption spectrum with temperature was observed. Borkowski and Ausloos<sup>1</sup> (313 and 334 nm) reported absorption cross sections at 329 K that are in agreement with the 298 K recommendation.

**Photolysis Quantum Yield and Product Studies:** The photolysis quantum yield for CF<sub>3</sub>CHO and the product branching ratios are wavelength dependent. Sellevåg et al.<sup>10</sup> determined the effective atmospheric photolysis quantum yield for CF<sub>3</sub>CHO using an outdoor photoreactor to be <0.02. Dodd and Watson-Smith<sup>3</sup> determined the products following photolysis at 313 nm to be  $\Phi_1 = 0.12$  and  $\Phi_2 = 0.021$ . Pearce and Whytock<sup>8</sup> reported  $\Phi_2 = 0$  for 313 nm photolysis. Richer et al.<sup>9</sup> studied the products formed following 254 nm photolysis and reported product yields of CHF<sub>3</sub> (14%), CF<sub>2</sub>O (80%), CO (65%), CO<sub>2</sub> (45%) and  $\Phi_2 = 0.14$ . At 366 nm, Richer et al.<sup>9</sup> observed only a small degree of dissociation after >6 hours of photolysis. Chiappero et al.<sup>2</sup> reported photolysis quantum yields of  $\Phi_1 = 0.41 \pm 0.07$  and  $\Phi_2 = 0.38 \pm 0.07$  at 254 nm and  $\Phi_1 = 0.17 \pm 0.03$  and  $\Phi_2 \sim 0$  at 308 nm. Quantum yields of  $\Phi_1 = 0.15 \pm 0.03$  and  $\Phi_2 < 0.02$  are recommended at 313 nm.

## E25. $CF_3C(O)F$ (trifluoroacetyl fluoride)

[Back to Index](#)

(1)

(2)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of trifluoroacetyl fluoride,  $CF_3C(O)F$ , has been measured at room temperature by Meller et al.<sup>3</sup> (200–281 nm), Rattigan et al.<sup>4</sup> (200–295 nm), and Malanca et al.<sup>2</sup> (200–340 nm). The cross sections from Meller et al.<sup>3</sup> and Malanca et al.<sup>2</sup> are in good agreement in the spectral region 200–260 nm. The position of the absorption maximum near 213 nm reported by Rattigan et al.<sup>4</sup> is shifted by ~3 nm to longer wavelengths as compared to that reported by Meller et al.<sup>3</sup> and Malanca et al.<sup>2</sup> The cross sections from these studies differ by 20 to 30% at wavelengths >260 nm.

The temperature dependence of the absorption spectrum has been reported by Rattigan et al.<sup>4</sup> (233–293 K) and Malanca et al.<sup>2</sup> (238–300 K). For wavelengths >210 nm, the absorption cross section decreases with decreasing temperature. The recommended absorption cross sections in Table 4E-12 are taken from Malanca et al.<sup>2</sup> in the region 200–260 nm at 300 and 238 K. In the region 265–280 nm, the data of Meller<sup>3</sup> are recommended at 297 K and those of Rattigan et al.<sup>4</sup> at 238 K. An uncertainty factor of 1.2 ( $2\sigma$ ) is recommended for the 297 and 300 K cross section data given in Table 4E-12.

*Photolysis Quantum Yield and Product Studies:* Bierbrauer et al.<sup>1</sup> measured the quantum yield of disappearance of  $CF_3C(O)F$  at 240 and 254 nm to be  $\Phi_1 + \Phi_2 = 1.02 \pm 0.05$ . It is assumed that this applies over the wavelength region 200–300 nm.

**Table 4E-12. Recommended Absorption Cross Sections of  $\text{CF}_3\text{C(O)F}$  at 297/300 K and 238 K**

$\lambda$ (nm)	$10^{20} \sigma$ ( $\text{cm}^2$ ) 297 and 300 K	$10^{20} \sigma$ ( $\text{cm}^2$ ) 238 K

## E26. $\text{CF}_3\text{C(O)Cl}$ (trifluoroacetyl chloride)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of trifluoroacetyl chloride,  $\text{CF}_3\text{C(O)Cl}$ , has been measured at room temperature by Maricq and Szente<sup>2</sup> (190–342 nm), Rattigan et al.<sup>4</sup> (220–330 nm), Meller and Moortgat<sup>3</sup> (200–329 nm), and Malanca et al.<sup>1</sup> (200–325 nm). The UV absorption spectrum has a band between 215 and 330 nm with a maximum around 255 nm and the shoulder of a stronger band apparent between 200 and 215 nm. The cross section data from the Rattigan et al.,<sup>4</sup> Meller and Moortgat,<sup>3</sup> and Malanca et al.<sup>1</sup> studies are in agreement for wavelengths >240 nm, with the agreement better than 5% between 240 and 315 nm. The Meller and Moortgat<sup>3</sup> cross sections are greater than those of Rattigan et al.<sup>4</sup> and Malanca et al.<sup>1</sup> by ~65% near the absorption minimum at 215 nm. Maricq and Szente<sup>2</sup> report a very noisy spectrum with an absorption maximum of  $(4.6 \pm 0.7) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  at ~255 nm compared to  $6.8 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  by Rattigan et al.<sup>4</sup> and Malanca et al.<sup>1</sup> and  $6.7 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  by Meller and Moortgat.<sup>3</sup>

The temperature dependence of the absorption spectrum has been measured by Rattigan et al.<sup>4</sup> (233, 253 and 296 K), Meller and Moortgat<sup>3</sup> (223, 248, 273 and 298 K), and Malanca et al.<sup>1</sup> (253 and 300 K). These studies

show a decrease of the absorption cross sections with decreasing temperature in the wavelength regions below ~215 nm and above 255 nm. For the region between 215 and 255 nm, a very slight decrease in absorption cross section with decreasing temperature was observed in these studies. The recommended absorption cross sections in Table 4E-13 are taken from Malanca et al.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* Maricq and Szente<sup>2</sup> photolysed CF<sub>3</sub>C(O)Cl at 193 and 248 nm in O<sub>2</sub>/N<sub>2</sub>/C<sub>2</sub>H<sub>6</sub> mixtures and measured the formation of the products CF<sub>3</sub>O<sub>2</sub>, HCl, and CO. They report  $\Phi_2 + \Phi_3 = 1.01 \pm 0.11$  at 193 nm and  $\Phi_2 + \Phi_3 = 0.92 \pm 0.08$  at 248 nm where channel 2 was determined to be the major dissociation pathway at both wavelengths. Meller and Moortgat<sup>3</sup> photolysed CF<sub>3</sub>C(O)Cl at 254 nm in N<sub>2</sub> and air/C<sub>2</sub>H<sub>6</sub> mixtures over the pressure range 100–760 Torr and measured the formation of the stable end-products CF<sub>3</sub>Cl, C<sub>2</sub>F<sub>6</sub>, Cl<sub>2</sub> and CO. They report the quantum yield for the disappearance of CF<sub>3</sub>C(O)Cl to be  $\Phi_1 + \Phi_2 = 0.95 \pm 0.05$ . Weibel et al.<sup>5</sup> photolysed CF<sub>3</sub>C(O)Cl at 254 and 280 nm in N<sub>2</sub> and air/C<sub>2</sub>H<sub>6</sub> mixtures in the pressure range 100–600 Torr and measured the formation of the products CF<sub>3</sub>Cl, C<sub>2</sub>F<sub>6</sub>, and CO. A quantum yield for the decomposition of CF<sub>3</sub>C(O)Cl =  $\Phi[CF_3Cl + 2C_2F_6] = 0.98 \pm 0.13$ ,  $\Phi_1 + \Phi_2 = 0.95 \pm 0.05$  was obtained. The quantum yields measured by Meller and Moortgat<sup>3</sup> and Weibel et al.<sup>5</sup> were independent of total pressure. There are no quantum yield data in the atmospherically important wavelength range >290 nm.

## E27. $\text{CF}_3\text{OONO}_2$ (trifluoromethyl peroxy nitrate)

[Back to Index](#)

(1)

(2)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption cross sections of trifluoromethyl peroxy nitrate,  $\text{CF}_3\text{OONO}_2$ , have been measured at room temperature by Kopitzky et al.<sup>1</sup> (185–340 nm) and over the temperature range 233–300 K by Malanca et al.<sup>2</sup> (200–340 nm). The UV absorption spectrum over this wavelength range consists of at least two overlapping continuous absorption bands with maxima below 185 nm and near 260 nm. The spectrum exhibits continuously decreasing absorption cross sections over the 185–340 nm wavelength range. The absorption spectra measured at room temperature in these studies are in agreement for wavelengths  $\leq 290$  nm, to within 10% or better. At longer wavelengths, significant discrepancies in the reported spectra are evident, which is most likely due to differences in measurement precision and the accuracy of corrections applied to account for the  $\text{NO}_2$  impurity absorption. The recommended room temperature cross sections given in Table 4E-14 are taken from Kopitzky et al.

**Table 4E-14. Recommended Absorption Cross Sections of  $\text{CF}_3\text{OONO}_2$  at 301 K**

$\lambda$ (nm)	$10^{20}\sigma$ (cm $^2$ )	$\lambda$ (nm)	$10^{20}\sigma$ (cm $^2$ )
185	430	265	8.2

Note:

Kopitzky et al.<sup>1</sup>

Malanca et al.<sup>2</sup> reported absorption spectra at 300, 294, 273, 253, and 233 K. The measured spectra were corrected for an unspecified contribution from  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  impurity absorption, which is particularly important at wavelengths  $>\sim 260$  nm. A decrease in absorption cross section over the wavelength range 260 to 340 nm with decreasing temperature was reported. The temperature dependence was parameterized using the empirical expression

$$\log_{10}(\sigma) = B \times T + \log_{10} \sigma_0$$

where  $\sigma$  and  $\sigma_0$  are the cross sections in  $\text{cm}^2$  molecule $^{-1}$  at temperatures T and 0 K, respectively. Malanca et al. reported  $\sigma(0\text{ K})$  and B parameters at selected wavelengths as given in Table 4E-15.

**Table 4E-15. Recommended CF<sub>3</sub>OONO<sub>2</sub> Absorption Spectrum Temperature Dependence**

$\lambda$ (nm)	$10^3 B$ (K <sup>-1</sup> )	$10^{20} \sigma_0(0 \text{ K})$ (cm <sup>2</sup> molecule <sup>-1</sup> )
290	6.8	$1.2 \times 10^{-2}$
295	8.3	$2.9 \times 10^{-3}$
300	10.5	$4.4 \times 10^{-4}$
305	12	$8.4 \times 10^{-5}$
310	14	$1.9 \times 10^{-5}$
315	16.4	$2.9 \times 10^{-6}$
320	18	$6.0 \times 10^{-7}$
325	22	$3.7 \times 10^{-8}$
330	26	$1.3 \times 10^{-9}$

Note:

Malanca et al.<sup>2</sup>*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E28. CF<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> (trifluoroperoxyacetyl nitrate)**[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of trifluoroperoxyacetyl nitrate (FPAN), CF<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub>, has been measured at room temperature by Libuda and Zabel<sup>2</sup> (227–305 nm) and Kopitzky et al.<sup>1</sup> (190–295 nm). These studies are in agreement for wavelengths >260 nm, but have systematic differences at shorter wavelengths with the Kopitzky et al. cross sections being lower. Over this wavelength range, the CF<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> spectrum is red shifted by ~5 nm from the CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> spectrum. The recommended absorption cross sections in Table 4E-16 are averages over 5 nm intervals of the 0.6 nm resolution spectrum reported by Libuda and Zabel.<sup>2</sup> As reported by Libuda and Zabel,<sup>2</sup> the estimated cross section uncertainties are ~10% for wavelengths <290 nm and 15 to 45% in the region 295–305 nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation, although excitation in the UV is expected to break the weak O-ONO<sub>2</sub> bond.

#### E29. $\text{CF}_3\text{CH}_2\text{CHO}$ (3,3,3-trifluoropropionaldehyde)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of 3,3,3-trifluoropropionaldehyde,  $\text{CF}_3\text{CH}_2\text{CHO}$ , has been measured at room temperature by Sellevåg et al.<sup>3</sup> (200–400 nm), Chiappero et al.<sup>2</sup> (230–355 nm), and Antíñolo et al. (230–350 nm).<sup>1</sup> The continuous absorption spectrum has weak diffuse band structure between 270 and 343 nm. The reported spectra are in reasonable agreement, with the cross sections from Sellevåg et al. ~6% greater than the values reported by Chiappero et al. and Antíñolo et al. near the peak of the spectrum. The spectrum reported by Antíñolo et al. is blue shifted by ~1 nm relative to the other two studies. The data reported for the wavelength region above 340 nm are in poor agreement. The recommended 298 K absorption cross sections given in Table 4E-17 were taken from Sellevåg et al.<sup>3</sup>

Chiappero et al.<sup>2</sup> measured the temperature dependence of the absorption spectrum over the range 249–297 K and reported no discernible variation of cross section with temperature. Antíñolo et al. measured the spectrum over the temperature range 269–323 K and reported a decrease in absorption cross sections with decreasing temperature between 260 and 330 nm. No recommendation is given for the spectrum temperature dependence.

*Photolysis Quantum Yield and Product Studies:* Sellevåg et al.<sup>3</sup> reported the effective atmospheric photolysis quantum yield for  $\text{CF}_3\text{CH}_2\text{CHO}$  using an outdoor photoreactor to be <0.02. The quantum yields for channels 1 and 2 were determined by Chiappero et al.<sup>2</sup> to be  $\Phi_1 = 0.38 \pm 0.09$  and  $\Phi_2 = 0.36 \pm 0.07$  for 254 nm photolysis and  $\Phi_1 = 0.04 \pm 0.01$  and  $\Phi_2 \sim 0$  at 308 nm in 700 Torr of  $\text{N}_2$  bath gas.

**E30. CF<sub>3</sub>C(O)OH (trifluoroacetic acid)**[Back to Index](#)

(Reccomendation: 06-2, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of trifluoroacetic acid, CF<sub>3</sub>C(O)OH, was measured at room temperature over the wavelength range 200–280 nm by Rattigan et al.,<sup>1</sup> the only study available, using diode array spectroscopy. The spectrum exhibits an absorption band with a broad maximum near 220 nm. The absorption spectrum of CF<sub>3</sub>C(O)OH is red shifted from the CH<sub>3</sub>C(O)OH spectrum and has lower absorption cross sections. The recommended absorption cross sections in Table 4E-18 are from Rattigan et al.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E34. CF<sub>2</sub>=CF<sub>2</sub> (tetrafluoroethylene)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of tetrafluoroethylene, CF<sub>2</sub>=CF<sub>2</sub>, has been measured at room temperature by Sharpe et al.<sup>3</sup> (185–209 nm), Orkin et al.<sup>2</sup> (164–220 nm), and Eden et al.<sup>1</sup> (113–330 nm). The spectrum shows a structured absorption band with five maxima between 170 and 200 nm (maximum near 188 nm). The spectra from Orkin et al.<sup>2</sup> and Eden et al.<sup>1</sup> agree to within 10% in the range 164–182 nm, 20% in the range 182–200 nm, and 10% in the range 203–205 nm. Above 195 nm, the absorption cross sections decrease monotonically toward longer wavelengths. The spectrum reported by Eden et al.<sup>1</sup> deviates from that of Orkin et al.<sup>2</sup> at wavelengths >200 nm, but the Eden et al. spectrum is very noisy in this region. The absorption spectrum reported by Sharpe et al.<sup>3</sup> is systematically shifted by 1 to 2 nm to shorter wavelengths relative to the Orkin et al.<sup>2</sup> spectrum. The recommended absorption cross sections given in Table 4E-22 are the mean of the data from Orkin et al.<sup>2</sup> and Eden et al.<sup>1</sup> for the region 164–205 nm and the data from Orkin et al.<sup>2</sup> in the region 206–220 nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E35. CF<sub>2</sub>=CFCF<sub>3</sub> (hexafluoropropene)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of hexafluoropropene, CF<sub>2</sub>=CFCF<sub>3</sub>, was measured at room temperature by Sharpe et al.<sup>3</sup> (185–209 nm), Orkin et al.<sup>2</sup> (164–222 nm), and Eden et al.<sup>1</sup> (115–330 nm). The spectrum has overlapping absorption bands between 140 and 220 nm with maxima at 155 and 158.5 nm ( $\sigma \approx 3 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ ), 166, and 180 nm. In the wavelength region 164–200 nm, the cross sections from Orkin et al.<sup>2</sup> and Eden et al.<sup>1</sup> agree to within 15%. In the region 185–200 nm, the cross sections from Orkin et al.,<sup>2</sup> Eden et al.,<sup>1</sup> and Sharpe et al.<sup>3</sup> agree to within 25%. Above 195 nm, the absorption cross sections decrease toward longer wavelengths. The spectrum reported by Eden et al.<sup>1</sup> deviates from that of Orkin et al.<sup>2</sup> at wavelengths >200 nm, but the Eden et al. spectrum is very noisy in this region. The recommended absorption cross sections given in Table 4E-23 are the mean of the data from Orkin et al.<sup>2</sup> and Eden et al.<sup>1</sup> for the region 164–199 nm and the data from Orkin et al.<sup>2</sup> in the region 200–222 nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**E36. NF<sub>3</sub> (nitrogen trifluoride)**[Back to Index](#)

(New Entry)

*Absorption Cross Sections:* The UV absorption spectrum of nitrogen trifluoride, NF<sub>3</sub>, has been measured at room temperature by Makeev et al.<sup>4</sup> (210–240 nm), Molina et al.<sup>5</sup> (180–250 nm), and Dillon et al.<sup>1</sup> (184–226 nm), and as a function of temperature by Papadimitriou et al.<sup>6</sup> (184.95–250 nm, 212–296 K). The room temperature spectra reported by Molina et al., Dillon et al., and Papadimitriou et al. are in good agreement over the common wavelength regions. The data from Makeev et al. are significantly greater than the other studies and are not considered in the recommendation. The room temperature spectrum from the Papadimitriou et al. study is given in Table 4E-24.

**Table 4E-24. Recommended Absorption Cross Sections of NF<sub>3</sub> at 296 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )
184.95	3.44
190	1.16
195	0.393
200	0.132
205	0.0454
210	0.0168
215	0.00698
220	0.00335
225	0.00154
230	0.000801
235	0.000485
240	0.000287
250	0.000111

Note:

184.95–250 nm: Papadimitriou et al.<sup>6</sup>

Papadimitriou et al. measured the spectrum temperature dependence over the range 212–296 K. They observed a systematic decrease in absorption cross section with decreasing temperature at all wavelengths included in their study. The absorption spectrum was parameterized using the empirical formula

$$\log_{10}(\sigma(\lambda, T)) = \sum_i A_i \lambda^i + (296 - T) \sum_i B_i \lambda^i$$

and the parameters are given in Table 4E-25. The parameterization is recommended here. The parameterization reproduces the Molina et al. and Dillon et al. datasets to better than ~10% at all wavelengths. An uncertainty factor of 1.1 (2 $\sigma$ ) for the room temperature absorption spectrum is assigned, which encompasses the range of the available experimental data.

**Table 4E-25. Recommended NF<sub>3</sub> UV Absorption Spectrum,  $\sigma(\lambda, T)$ , Parameterization**

I	$A_i$	$B_i$
0	-218.67	0.9261
1	4.03743	-0.0130187
2	-0.0295605	$6.096 \times 10^{-5}$
3	$9.596 \times 10^{-5}$	$-9.75 \times 10^{-8}$
4	$-1.3171 \times 10^{-7}$	$9.76 \times 10^{-12}$
5	$4.929 \times 10^{-11}$	—

Note:

Papadimitriou et al.<sup>6</sup>

NF<sub>3</sub> VUV absorption cross sections have been measured in the 126.6–178.6 nm wavelength region by La Paglia and Duncan<sup>3</sup> and at 147 nm by Inel.<sup>2</sup> The absorption cross section value reported by Inel is approximately a factor of 2 greater than that reported by La Paglia and Duncan. A recommended Lyman- $\alpha$  cross section of  $4.8 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> was obtained from an extrapolation of the La Paglia and Duncan data. An uncertainty factor of 1.5 (2 $\sigma$ ) is recommended, based primarily on the fact that there are no direct measurements at Lyman- $\alpha$ .

*Photolysis Quantum Yield and Product Studies:* Dillon et al.<sup>1</sup> measured the F atom quantum yield in the 193 nm photolysis of NF<sub>3</sub> to be  $1.03 \pm 0.05$ . A unit photolysis quantum yield for the loss of NF<sub>3</sub> is recommended over the wavelength range most critical for its atmospheric photolysis, i.e., 190–230 nm.

## SECTION 4F. CLO<sub>x</sub> PHOTOCHEMISTRY

### F1. Cl<sub>2</sub> (molecular chlorine)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The recommended absorption cross sections of Cl<sub>2</sub>, molecular chlorine, are taken from the work of Maric et al.,<sup>11</sup> who studied the absorption spectrum in the range 200–550 nm using a spectral resolution of 0.2 nm at 298 K. These authors also measured banded features in the range 476–496 nm at 0.04 nm resolution. The absorption cross sections can be calculated in the range 250–550 nm at various temperatures with the expression derived from their study and previous investigations:

$$\sigma = 10^{-20} \alpha^{0.5} \left\{ 27.3 \exp \left( -99.0 \alpha \left( \ln \left( \frac{329.5}{\lambda} \right) \right)^2 \right) + 0.932 \exp \left( -91.5 \alpha \left( \ln \left( \frac{406.5}{\lambda} \right) \right)^2 \right) \right\}$$

where  $\alpha = \tanh(402.7/T)$ ;  $\lambda$  in nm,  $250 < \lambda < 550$  nm, and T in K;  $300 \text{ K} > T > 195 \text{ K}$ . Cross sections calculated for 298 K are given in Table 4F-1. For convenience, some room temperature values are listed in the table. Ganske et al.<sup>8</sup> have also measured the cross sections at room temperature and the agreement with the recommended values is excellent. These two sets of data also agree well with earlier recommendations, which were based on the work of Seery and Britton,<sup>14</sup> which is in turn in good agreement with the results reported by Gibson and Bayliss,<sup>9</sup> Fergusson et al.,<sup>7</sup> and Burkholder and Bair.<sup>1</sup> At wavelengths  $> 250$  nm, the absorption cross sections measured at room temperature by Hubinger and Nee<sup>10</sup> are in excellent agreement with the values of Maric et al.<sup>11</sup> However, in the range 200–250 nm the cross sections deviate considerably between these groups. Room temperature cross sections have also been obtained by Roxlo and Mandl<sup>13</sup> for the range 170–214 nm. The low resolution absorption cross sections reported by Chen and Zhu<sup>3,4</sup> and Chen et al.<sup>5</sup> for the 300–420 nm region at 5 and 10 nm intervals and measured for the calibration of quantum yield measurements of some carbonyl compounds deviate by up to ~30% from those reported by Maric et al.<sup>11</sup>

*Photolysis Quantum Yield and Product Studies:* The estimated atmospheric photodissociation rate is only weakly affected by the temperature dependence of the spectrum. Chininin<sup>6</sup> measured an upper limit of 5% for the branching ratio for excited atomic Cl\*(<sup>2</sup>P<sub>1/2</sub>) at 351 nm in agreement with earlier studies by Busch et al.<sup>2</sup> at 347.1 nm and Park et al.<sup>12</sup> at 308 and 340–355 nm, who determined an upper limit for Cl\* formation of 0.01.

## F2. ClO (chlorine monoxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

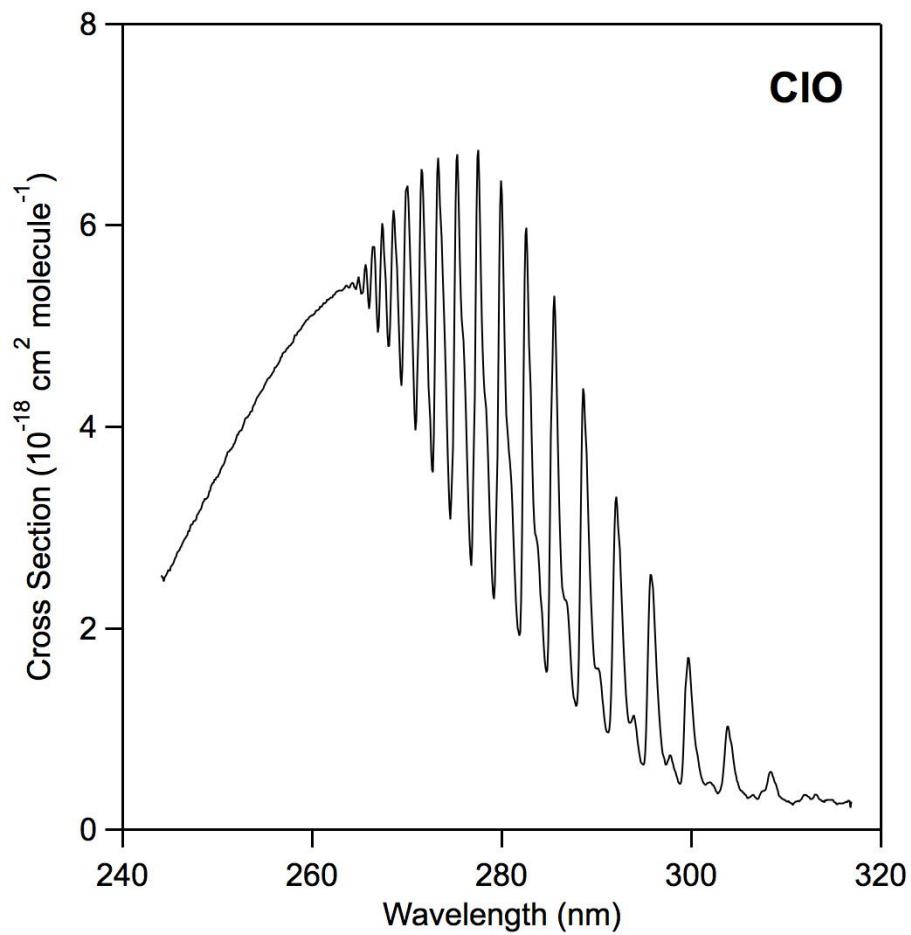

*Absorption Cross Sections:* The UV absorption spectrum of chlorine monoxide, ClO, shown in Figure 4-1, is partly composed of a continuum absorption band from 210 nm to the maximum near 265 nm, and a characterized banded structure of a strong A <sup>2</sup>Π<sub>3/2</sub> ← X <sup>2</sup>Π<sub>3/2</sub> transition, superposing a weak A <sup>2</sup>Π<sub>1/2</sub> ← X <sup>2</sup>Π<sub>1/2</sub> system between 265 nm and 315 nm. Watson<sup>15</sup> has reviewed the cross section measurements prior to 1977. The more recent measurements yield results in reasonable agreement with the earlier studies by Mandelman and Nicholls<sup>8</sup> (250–310 nm), Wine et al.<sup>16</sup> (near 283 nm), Rigaud et al.<sup>10</sup> (272–324 nm), Jourdain et al.<sup>5</sup> (272–320 nm), Barton et al.<sup>1</sup> (274–306 nm) at 315 K, Lang et al.<sup>6</sup> (253.7 and 257.7 nm), Sander and Friedl<sup>11</sup> (244–317 nm, 275.2 nm) at 220, 298, and 400 K, Trolier et al.<sup>14</sup> (220–350 nm, 282.65 nm) over the temperature range 200–263 K, and Simon et al.<sup>13</sup> (240–310 nm). The peak cross section at the maximum of the continuum (near 265 nm) is  $5.2 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup>, based on the average of the results from Jourdain et al., Sander and Friedl, Trolier et al., Simon et al., and Johnston et al.<sup>4</sup> At 257.7 nm an average value of  $(4.86 \pm 0.04) \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> was calculated from the data of the Mandelman and Nicholls, Lang et al., Sander and Friedl, Trolier et al., and Simon et al. studies. It should be noted that the cross sections in the structured region of the spectrum are extremely dependent on instrument resolution. Figure 4F-1 shows a spectrum of ClO based on the data of Sander and Friedl. The recommended absorption cross sections listed in Table 4F-2 are averages over 1 nm intervals of the continuous and banded regions of the spectrum measured at a resolution of 0.3 nm by Sander and Friedl. In Table 4F-3 the absorption cross sections for the band heads of the v',v'' = 1,0 to 21,0 transitions measured at various spectral resolutions are compared.

The cross sections of the continuum are independent of temperature (Trolier et al.<sup>14</sup>), while the structured part of the spectrum is extremely temperature dependent, the bands sharpen and increase in intensity with decreasing temperature. Sander and Friedl<sup>11</sup> measured the temperature dependence at the peak of the 12,0 band (275.2 nm) over the range 220–400 K and Trolier et al.<sup>14</sup> measured the temperature dependence at the peak of the 9,0 band (282.65 nm) over the range 200–298 K. Clyne and Coxon<sup>2</sup> determined the following relationship for the 11,0 sub-band relative to the 294 K value for the temperature range 294–240 K

$$\sigma_{294} / \sigma_T = 1 + 0.0036 (T - 294)$$

Maric and Burrows<sup>9</sup> performed an analysis of the ClO spectrum and developed an analytical approach that allows the calculation of the UV absorption spectrum as a function of temperature and spectral resolution.

*Photolysis Quantum Yield and Product Studies:* The calculations of Coxon et al.<sup>3</sup> and Langhoff et al.<sup>7</sup> indicate that photodecomposition of ClO accounts for at most 2 to 3% of the total destruction rate of ClO in the stratosphere, which occurs predominantly by reaction with oxygen atoms and nitric oxide. The photodissociation of thermal ClO radicals in the wavelength range 237 < λ < 270 nm was studied by Schmidt et al.<sup>12</sup> using REMPI. Cl(<sup>2</sup>P<sub>3/2,1/2</sub>) and O(<sup>1</sup>D) were formed with unity quantum yield. The threshold wavelength for O(<sup>1</sup>D) production was determined to be 263.4 nm. In the structured region of the spectrum oxygen atoms are formed in the triplet ground state.

### F3. ClOO (chlorine superoxide)

[Back to Index](#)

(Recommendation: 92-20, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Johnston et al.<sup>2</sup> measured the absorption spectrum of the ClOO radical, chlorine superoxide, using a molecular modulation technique and determined absorption cross sections using a complex kinetic scheme interpretation. More recently, Mauldin et al.<sup>3</sup> (220–280 nm, 191 K) and Baer et al.<sup>1</sup> (240–300 nm, 300 K) have reported cross section measurements. These two studies are in reasonable agreement with cross section values that are more than twice the earlier Johnston et al.<sup>2</sup> values. The recommended cross sections in Table 4F-4 are taken from Mauldin et al.<sup>3</sup>

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield is assumed to be unity over the entire UV absorption band.

	→ ClOO	-10 kJ mol <sup>-1</sup>	All	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of chlorine dioxide, OCIO, is characterized by a series of well developed progressions of bands extending from ~280 to 480 nm corresponding to the A (<sup>2</sup>A<sub>2</sub>) (i,j,k) ← X (<sup>2</sup>B<sub>1</sub>) (0,0,0) vibronic transitions. The spectroscopy of this molecule has been studied extensively and the quantum yield for photodissociation appears to be unity throughout the above wavelength range. See for example, the review by Watson.<sup>23</sup> Birks et al.<sup>3</sup> have estimated an atmospheric photodissociation half-life of OCIO of a few seconds. The measurement of absorption spectra at temperatures between 200 and 378 K has been the subject of many studies as summarized in Table 4F-5.

**Table 4F-5. Summary OCIO Cross Section Studies**

Type:

A: Absolute cross section determination

R: Relative cross section determination

Absorption cross sections at 10 nm intervals for the region 270–440 nm and at 333 K have been reported by Knauth et al.,<sup>15</sup> and for the 351.5 nm maximum at room temperature by Clyne and Coxon<sup>7</sup> and Basco and Dogra.<sup>1</sup> The absorption cross sections of Wahner et al.<sup>22</sup> obtained at a resolution of 0.25 nm, and at 204, 296, and 378 K have been used by Hubinger and Nee,<sup>14</sup> Frost et al.,<sup>13</sup> and Marston et al.<sup>18</sup> for the calibration of their relative spectra. The values at the peaks of the main vibrational bands a(0) to a(26) (i.e., A (<sup>2</sup>A<sub>2</sub>) (i,0,0) ← X (<sup>2</sup>B<sub>1</sub>) (0,0,0), i = 0 to 26) reported by Wahner et al.<sup>22</sup> have been selected as recommended absorption cross sections of OCIO in earlier JPL evaluations. More recently, Kromminga et al.<sup>16</sup> reported high and medium resolution absorption spectra at five temperatures between 213 and 293 K obtained using Fourier transform spectroscopy, which has the advantage of accurate wavelength calibration. There is a clear wavelength shift (~0.2–0.5 nm) between the spectra of Kromminga et al.<sup>16</sup> and Wahner et al.<sup>22</sup> that can't be explained by the shift between measurements in air and in vacuum. The absorption cross sections for the band peaks a(3) to a(26) reported by Kromminga et al. are smaller by 5–10% than those reported by Wahner et al.<sup>22</sup> A decrease of the temperature causes a sharpening of the vibrational bands and an increase of the peak cross sections as observed between 293 and 213 K by Kromminga et al.<sup>16</sup> and between 378 and 200 K by Wahner et al.<sup>22</sup>

The recommended absorption cross sections of OCIO in Table 4F-6 are averages over 1 nm intervals of the spectrum measured by Wahner et al.<sup>22</sup> (0.25 nm resolution). In Table 4F-7 are listed the band peaks at 213, 233, 253, 273, and 293 K recorded in the medium resolution (0.2–0.4 nm) spectra by Kromminga et al.<sup>16</sup> The values for the a(21) to a(16) bands at 293 K are the results of Bogumil et al.,<sup>6</sup> which were measured at medium resolution (0.24–0.44 nm) with the SCIAMACHY pre-flight satellite instrument and scaled to the

absorption cross sections measured by Kromminga et al.<sup>16</sup> In addition, the peak cross sections determined by Wahner et al.<sup>22</sup> are listed in Table 4F-8. Figure 4F-2 shows the spectrum of OCIO at 204 K based on the data of Wahner et al.<sup>22</sup>

VUV absorption cross sections have been measured by Basco and Morse,<sup>2</sup> (148–183 nm), Flesch et al.<sup>12</sup> (50–207 nm), Hubinger and Nee<sup>14</sup> (127–183 nm), and Marston et al.<sup>18</sup> (115–191 nm).

*Photolysis Quantum Yield and Product Studies:* The photochemistry of OCIO is extremely complex, with several electronic excited states involved in the photodissociation dynamics. Several channels have been observed at wavelengths important in the stratosphere, including O + ClO, Cl + O<sub>2</sub>, and isomerization to ClOO. Colussi<sup>8</sup> measured  $\Phi(\text{Cl})$  to be <0.01, and  $\Phi(\text{O}) = 1$  (within experimental error) for photolysis at 308 nm. Vaida et al.<sup>21</sup> and Rühl et al.<sup>20</sup> reported Cl atom production at 362 nm and Bishenden et al.<sup>4,5</sup> measured  $\Phi(\text{Cl})$  to be  $0.15 \pm 0.10$  around the same wavelength. In contrast, Lawrence et al.<sup>17</sup> report  $\Phi(\text{Cl})$  in the 359–368 nm region to be  $<5 \times 10^{-4}$ . This conclusion is supported by photofragment studies of Davis and Lee<sup>10</sup> between 350 and 475 nm, who report  $\Phi(\text{Cl}) < 0.2\%$  in the wavelength range 350–370 nm, rising to a maximum of  $3.9 \pm 0.8\%$  near 404 nm. In a later study, Davis and Lee<sup>9</sup> report a substantial yield of O<sub>2</sub>(<sup>1</sup>A<sub>g</sub>) and show that the branching ratio between O + ClO and Cl + O<sub>2</sub> depends on the OCIO(A <sup>2</sup>A<sub>2</sub>) excited state vibrational mode. Delmdahl et al.<sup>11</sup> measured the yield of nascent Cl atoms to be below 3.6% for photolysis in the 365–450 nm range. At  $\lambda < 365$  nm, there was a sharp increase of the Cl yield, which was attributed to the photolysis of vibrationally excited ClO ( $v \geq 4$ ).

The recommendation is to use a quantum yield value of unity for the production of O(<sup>3</sup>P) atoms in the range 270–480 nm. An upper limit for the Cl yield can be set at 0.04 for the wavelength range 365–450 nm. While accurate absorption cross section values are valuable for atmospheric measurements of OCIO abundance, the identity of the photodissociation products is only of minor importance in the context of atmospheric processes.

## F5. $\text{ClO}_3$ (chlorine trioxide)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The JPL-83 to JPL-90 recommendations for the absorption cross sections of the  $\text{ClO}_3$  radical, chlorine trioxide, were based on the work of Goodeve and Richardson.<sup>2</sup> Lopez and Sicre<sup>5</sup> have, however, since shown that the spectrum reported by Goodeve and Richardson is most likely that of  $\text{Cl}_2\text{O}_6$ . Thermochemical estimates by Colussi et al.<sup>1</sup> further corroborate this assignment.

Grothe and Willner<sup>3,4</sup> have reported the UV and IR spectra of  $\text{ClO}_3$  trapped in a neon matrix following thermal decomposition of  $\text{Cl}_2\text{O}_4$  or  $\text{FOClO}_3$ . By monitoring the amount of ClO formed as a photolysis product of  $\text{ClO}_3$ , they determined the absorption cross sections in the range 250–500 nm. The spectrum has a highly structured absorption band around 320 nm ( $\sigma \approx 3 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ ) and a second band around 425 nm ( $\sigma \approx 2.5 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ ) as depicted in the review article of Wayne et al.<sup>6</sup> A broad absorption spectrum between 280 and 450 nm peaking at ~300 nm ( $\sigma \approx 1.8 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ ) was recorded for  $\text{ClO}_3$  formed by radiolysis of aqueous solutions of chlorate ions. No recommendation is given for the absorption cross sections of  $\text{ClO}_3$  in the gas phase.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## F6. Cl<sub>2</sub>O (dichlorine monoxide)

[Back to Index](#)

Cl <sub>2</sub> O + hν → Cl + ClO	142 kJ mol <sup>-1</sup>	844 nm	(1)
→ Cl <sub>2</sub> + O( <sup>3</sup> P)	168 kJ mol <sup>-1</sup>	712 nm	(2)
→ Cl <sub>2</sub> + O( <sup>1</sup> D)	356 kJ mol <sup>-1</sup>	335 nm	(3)
→ O + 2Cl	411 kJ mol <sup>-1</sup>	291 nm	(4)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

**Absorption Cross Sections:** The UV/vis absorption spectrum of dichlorine monoxide, Cl<sub>2</sub>O, has been measured at room temperature by Goodeve and Wallace<sup>4</sup> (230–620 nm), Finkelnburg et al.<sup>3</sup> (220–650 nm), Martin and Gareis<sup>8</sup> (234–331 nm), Lin<sup>7</sup> (180–640 nm), Molina and Molina<sup>9</sup> (200–450 nm), Simon et al.<sup>17</sup> (236–320 nm), Smith et al.<sup>18</sup> (190–399 nm), and Papanastasiou et al.<sup>15</sup> (200–500 nm). The earlier data reported by Goodeve and Wallace,<sup>4</sup> Finkelnburg et al.,<sup>3</sup> and Martin and Gareis<sup>8</sup> deviate substantially from the more recent results and are not considered further in this evaluation. The spectrum measured by Simon et al.<sup>17</sup> was normalized to the data of Lin.<sup>7</sup> The spectrum measured by Papanastasiou et al. was scaled to a cross section value of  $1.96 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> at 255 nm. The spectrum exhibits three absorption bands in the UV/vis region. An asymmetrical band between ~220–380 nm with the maximum near 255 nm and a shoulder near 290 nm, and two weak bands at ~380–500 nm and ~500–650 nm with maxima near 420 nm and 550 nm, respectively. The absorption cross sections measured by Lin et al.,<sup>7</sup> Molina and Molina,<sup>9</sup> Knauth et al.,<sup>6</sup> Smith et al.,<sup>18</sup> and Papanastasiou et al. are in very good agreement, i.e., to within 10%, for the UV absorption band between 200 and ~350 nm. The values reported by Molina and Molina<sup>9</sup> and Knauth et al.<sup>6</sup> are somewhat larger than those reported by Lin,<sup>7</sup> which are larger than those reported by Smith et al.<sup>18</sup> The discrepancies between the various data sets are larger in the region of the absorption minimum.

The recommended absorption cross sections listed in Table 4F-9 are from Papanastasiou et al. in the region 200–500 nm, which are in good agreement with the Lin cross section data, and the data from Lin<sup>7</sup> in the region 510–640 nm. An uncertainty factor of 1.1 (2σ) is estimated for the 200–500 nm wavelength range. The estimated uncertainty encompasses the majority of the available experimental data.

Measurements at 298 and 333 K have been carried out by Knauth et al.<sup>6</sup> (200–500 nm). Johnsson et al.<sup>5</sup> (210–350 nm) measured the absorption spectrum in Ar matrices and reported a gas-phase absorption cross section at 260 nm. Papanastasiou et al.<sup>15</sup> reported spectra over the temperature range 201–296 K. They parameterized the Cl<sub>2</sub>O spectrum temperature dependence as the sum of six Gaussian functions (polynomial fits were also provided). Their parameterization is recommended and the fit expressions and coefficients can be obtained from their paper.

VUV absorption cross sections have been measured by Nee<sup>12</sup> (150–200 nm) and Motte-Tollet et al.<sup>11</sup> (128–190 nm).

**Photolysis Quantum Yield and Product Studies:** Sander and Friedl<sup>16</sup> have measured the quantum yield for production of O atoms to be  $0.25 \pm 0.05$ , using a broadband photolysis source extending from 180 nm to beyond 400 nm. The main photolysis products are Cl and ClO. Using a molecular beam technique, Nelson et al.<sup>13</sup> found Cl + ClO to be the only primary photodissociation channel at 308 nm, a major channel at 248 nm, and a minor channel at 193 nm. At 248 nm a fraction of the photoproduct ClO underwent spontaneous photodissociation. These authors found evidence that the dissociation to three atoms 2 Cl + O takes place at 193 nm and that some O(<sup>1</sup>D) atoms are generated as well. Papanastasiou et al.<sup>15</sup> measured a O(<sup>3</sup>P) + O(<sup>1</sup>D) quantum yield of  $0.85 \pm 0.15$  following 193 nm photolysis of Cl<sub>2</sub>O and a O(<sup>3</sup>P) quantum yield of  $0.20 \pm 0.03$  for 248 nm photolysis. An analysis presented in Papanastasiou et al. of the Feierabend et al.<sup>2</sup> measured ClO radical yield and its temporal profile following the 248 nm photolysis of Cl<sub>2</sub>O yielded a ClO yield of 0.8, a Cl atom yield of  $1.2 \pm 0.1$ , a O + 2Cl channel yield of 0.2, and a O + Cl<sub>2</sub> channel yield of <0.05. Zou et al.<sup>20</sup> studied the 193 and 248 nm photolysis of Cl<sub>2</sub>O using photofragment translational spectroscopy. They report a O(<sup>3</sup>P) quantum yield of 0.15 for 248 nm photolysis and that the O + 2Cl channel is a major product at 193 nm.

Nickolaisen et al.<sup>14</sup> reported that broadband photolysis at wavelengths >300 nm results in pressure-dependent ClO quantum yields, which was explained by the rapid intersystem crossing between two metastable states. These states undergo competitive dissociation to ClO + Cl and collisional relaxation to the ground state. Furthermore, these authors detected a transient absorption spectrum, which was assigned to a long-lived metastable triplet state of Cl<sub>2</sub>O. However, Moore et al.<sup>10</sup> estimated the lifetime of the metastable excited state to be much shorter. Chichinin<sup>1</sup> and Tanaka et al.<sup>19</sup> found evidence of ground state (<sup>2</sup>P<sub>3/2</sub>) and spin-orbit excited (<sup>2</sup>P<sub>1/2</sub>) atomic chlorine photoproducts. The implication is that the photodecomposition quantum yield

is less than unity at atmospherically relevant wavelengths in spite of the continuous nature of the absorption spectrum.

#### F7. ClOOCl (chlorine peroxide, dichlorine dioxide)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The gas-phase UV absorption spectrum of ClOOCl is continuous with a maximum near 245 nm, a minimum near 218 nm, and a weak diffuse shoulder in the wavelength region 280–300 nm. There are a number of studies that have reported UV absorption data for ClOOCl over a range of wavelengths or at specific wavelengths. Table 4F-10 summarizes the currently available studies. The ClOOCl UV absorption spectra reported by Basco and Hunt<sup>1</sup> and Molina and Molina<sup>18</sup> have been shown to contain systematic errors and are not considered further in this evaluation. In laboratory studies, ClOOCl has been produced in the gas-phase at low temperature as a product of the termolecular ClO radical self-reaction, ClO + ClO + M. Studies, to date, indicate that only one stable isomer of  $\text{Cl}_2\text{O}_2$  is produced in the ClO self-reaction and that this species is chlorine peroxide, ClOOCl, rather than ClOCIO or  $\text{ClCIO}_2$ . Using sub-millimeter wave spectroscopy, Birk et al.<sup>2</sup> have further established the structure of the reaction product to be ClOOCl. This is in general agreement with the quantum mechanical calculations of McGrath et al.,<sup>15,16</sup> Jensen and Odershede,<sup>10</sup> and Stanton et al.,<sup>27</sup> although the theoretical study by Matus et al.<sup>14</sup> found the  $\text{ClCIO}_2$  isomer to be more stable than ClOOCl by 3.1 kcal mol<sup>-1</sup> at 298 K.

\* Absorption cross section values at the peak of the spectrum, ~245 nm. Cross section data also given over the reported range of wavelengths. \$ Reported ClOOCl absorption spectrum without absolute cross section determination. # Solid-phase ClOOCl absorption spectrum measured in a Ne matrix. @ ClOOCl absorption spectrum at wavelengths reported at >310 obtained using a log-linear extrapolation. & ClOOCl cross section obtained assuming a unit photolysis quantum yield. && Product of absorption cross section and Cl-atom-producing channel:  $\sigma \times \varphi_{\text{Cl}}$ .

Cox and Hayman,<sup>6</sup> Burkholder et al.,<sup>4</sup> DeMore and Tschiukow-Roux,<sup>7</sup> Bloss et al.,<sup>3</sup> and Papanastasiou et al.<sup>21</sup> report absolute ClOOCl cross section,  $\sigma(\lambda)$ , values over a substantial range of wavelengths. The studies of Permien et al.,<sup>22</sup> Vogt and Schindler,<sup>30</sup> Huder and DeMore,<sup>9</sup> McKeachie et al.,<sup>17</sup> and Pope et al.<sup>25</sup> report absorption spectra normalized to 245 nm. von Hobe et al.<sup>31</sup> report a solid-phase ClOOCl UV absorption spectrum measured in a Ne matrix at ~10 K with reported cross sections obtained by normalization using the 245 nm cross section recommended in JPL 06-2<sup>26</sup> for the gas-phase spectrum.

Discrepancies in the wavelength dependence of the ClOOCl absorption spectrum at wavelengths >300 nm, the region that is most critical for atmospheric photolysis rate calculations, exist and most likely originate from uncertainties in corrections for spectral interferences by reactant precursors ( $\text{O}_3$ ,  $\text{Cl}_2\text{O}$ , and  $\text{Cl}_2$ ) and impurities ( $\text{OCIO}$ ,  $\text{Cl}_2$ , and  $\text{Cl}_2\text{O}_3$ ) formed in the ClOOCl source chemistry. Near the peak, the reported spectra are in reasonable agreement. The studies of Cox and Hayman, Burkholder et al., DeMore and Tschiukow-Roux, Vogt and Schindler, and McKeachie et al. show systematic deviations that are possibly consistent with spectral interference due to minor absorption by  $\text{Cl}_2\text{O}$  and, in the cases of Cox and Hayman, Burkholder et al., and McKeachie et al., possibly  $\text{Cl}_2\text{O}_3$ . At  $\lambda > 300$  nm, the ClOOCl spectrum is weaker and more sensitive to spectral interferences from impurities, in particular  $\text{Cl}_2$ . The studies of Burkholder et al. and DeMore and Tschiukow-Roux are the only pre-2007 gas-phase studies that report cross section data at  $\lambda > 360$  nm. Pope et al. developed a method to isolate bulk samples of ClOOCl in which ClOOCl is produced in the gas-phase and condensed at low temperatures. Pope et al. measured gas-phase UV spectra that are due mostly to  $\text{Cl}_2$  and ClOOCl absorption following the warming of the condensate. The spectra were analyzed using a Gaussian fitting procedure and they report a ClOOCl absorption spectrum that decreases rapidly at  $\lambda > 320$  nm with a cross section at 350 nm that is a factor of 6 lower than recommended in JPL-2006. The von Hobe et al. matrix study used the Pope et al. method to prepare their ClOOCl samples and Raman spectroscopy to evaluate the spectral contribution from  $\text{Cl}_2$  impurities. They report a ClOOCl spectrum with significant absorption at wavelengths out to 400 nm. von Hobe et al. suggest that Pope et al. mistakenly attributed a long-wavelength ClOOCl spectral feature to  $\text{Cl}_2$  impurity.

The study of Papanastasiou et al.,<sup>21</sup> which is in generally good agreement with the earlier studies, was carried out using diode array spectroscopy and laser photolysis to generate ClO radicals. The spectral analysis utilized reaction stoichiometry and three observed isosbestic points to account for chemical species, including  $\text{Cl}_2$ , which appear to represent an interference to a greater or lesser degree in all pre-2009 studies. The isosbestic point observed at 408.5 nm shows that ClOOCl absorbs measurably at wavelengths longer than 350 nm.

The study of Young et al.,<sup>34</sup> which was normalized to the cross section measured by Papanastasiou et al. at 245 nm, is in essentially perfect agreement with the latter from 200 nm to 310 nm and diverges from it somewhat at longer wavelengths. Young et al. prepared and purified ClOOCl using the methods described by Pope et al.<sup>25</sup> and extended the wavelength range into the visible, where their stated errors are relatively small. Young et al. corrected for  $\text{Cl}_2$  absorption by using its structured visible absorption spectrum, which they recently reported.<sup>35</sup>

Lower limits to the absolute cross sections have been measured recently at specific wavelengths by a new experimental method involving pulsed laser photolysis of ClOOCl in a molecular beam combined with mass spectrometric detection to determine  $\sigma(\lambda)\Phi(\lambda)$ , where  $\Phi(\lambda)$  is the ClOOCl photolysis quantum yield (see Chen et al.<sup>5</sup>). This new method is not sensitive to spectral interference from  $\text{Cl}_2$ . It yields the lower-limit for the ClOOCl cross sections, assuming  $\Phi(\lambda) = 1$ , which is thought to be a good assumption. Measurements by Chen et al.<sup>5</sup>, Lien et al.,<sup>13</sup> and Jin et al.<sup>11</sup> are slightly higher than, but in good agreement with, the data of

Papanastasiou et al.<sup>21</sup> Measurements over limited temperature ranges indicate that the cross sections are only weakly dependent on temperature.

Wilmouth et al.<sup>32</sup> used flow-tube and atomic resonance fluorescence techniques to measure Cl-atom production when ClOOCl is photolyzed at 248, 308, and 352 nm. By scaling their signals to the known Cl-atom yield in the photolysis of Cl<sub>2</sub> or the literature cross section at the peak of the ClOOCl absorption spectrum, they obtained the product of the ClOOCl absorption cross section and the quantum yield for the Cl-atom production channel,  $\sigma(\lambda)\phi_{\text{Cl}}(\lambda)$ , at the three wavelengths. It is noteworthy that the Cl<sub>2</sub> concentration was monitored in situ using fluorescence excited by the resonance lamp, and appropriate corrections to the Cl-atom yields were made. By assuming  $\phi_{\text{Cl}}(\lambda) = 1$ , they obtain the lower limit to the absorption cross section. Analyzed in this way, their lower limit cross sections at the three wavelengths are a little lower than the cross sections reported by Papanastasiou et al.,<sup>21</sup> although the agreement is better when quantum yields (see below) are considered.

The recommended ClOOCl absorption cross sections are based on the measurements of Papanastasiou et al.<sup>21</sup> (which were corrected on the basis of the isosbestic analysis), Wilmouth et al.<sup>32</sup> (which were corrected on the basis of in situ monitoring of Cl<sub>2</sub>), and Chen et al.,<sup>5</sup> Lien et al.,<sup>13</sup> and Jin et al.<sup>11</sup> (which are not susceptible to interfering species), and Young et al.<sup>33</sup> (which were normalized to the 245 nm value of Papanastasiou et al.<sup>21</sup>). The data of Papanastasiou et al.<sup>21</sup> and Wilmouth et al.<sup>32</sup> tend to be a little higher than the previous measurements, but somewhat lower than the measurements of Chen et al.,<sup>5</sup> Lien et al.,<sup>13</sup> and Jin et al.<sup>11</sup> Bloss et al.<sup>3</sup> measured a value for  $\sigma(210 \text{ nm})$  in a pulsed photolysis ClO + ClO + M kinetics study over the temperature range 183–245 K that is similar to the current recommendation. The recommended values (taken from Papanastasiou et al.<sup>21</sup> for 200–310 nm and Young et al.<sup>34</sup> for 510–535 nm) for the temperature range 190–250 K are listed in Table 4F-11. Near 310 nm, the measurements of Papanastasiou et al. (including an isosbestic point), Wilmouth et al., Chen et al., and Young et al. are in very good agreement; for  $\lambda > 310 \text{ nm}$ , the data of Young et al. begins to diverge from the others and the relative errors grow larger. A log-linear interpolation from 310 to 510 nm gives a good representation of all of the data, including the isosbestic point at 408.5 nm. Data at  $310 < \lambda < 510 \text{ nm}$  can be estimated from the formula  $\sigma(\lambda) = 4.05 \times 10^{-19} \times \exp[-0.0357 \times (\lambda - 310)]$ , where  $\lambda$  is in nm and  $\sigma$  is in units of  $\text{cm}^2 \text{ molecule}^{-1}$ .

*Cross Section Uncertainties:* The estimated uncertainty factor is 1.35 over the entire wavelength range from 200 to 535 nm.

*Photolysis Quantum Yields and Product Studies:* Molina et al.<sup>19</sup> reported a quantum yield,  $\Phi$ , of approximately unity ( $1.03 \pm 0.12$ ) for the Cl + ClOO pathway from a flash photolysis study at 308 nm, in which the yield of Cl atoms was measured using time-resolved atomic resonance fluorescence. These results are in agreement with the steady-state photolysis study of Cox and Hayman.<sup>6</sup> Plenge et al.<sup>24</sup> measured the primary products from ClOOCl photolysis at 250 and 308 nm using photoionization mass spectrometry. At both wavelengths 2Cl + O<sub>2</sub> was observed as the exclusive product channel corresponding to a primary Cl quantum yield near unity at 250 nm ( $\Phi_{\text{Cl}} \geq 0.98$ ) and at 308 nm ( $\Phi_{\text{Cl}} \geq 0.90$ ). At both photolysis wavelengths the pathway leading to ClO was not observed corresponding to  $\Phi_{\text{ClO}} \leq 0.02$  at 250 nm and  $\Phi_{\text{ClO}} \leq 0.10$  at 308 nm.

In a molecular beam/flash-photolysis study Moore et al.<sup>20</sup> used photofragment translational spectroscopy to measure the relative Cl:ClO product yields from which they derived branching ratios for both photolysis channels ClOO + Cl and ClO + ClO. At 248 nm, they obtained  $0.88 \pm 0.07$  and  $0.12 \pm 0.07$  respectively, and at 308 nm,  $0.90 \pm 0.1$  and  $0.10 \pm 0.01$ . Huang et al.<sup>8</sup> also used photofragment translational spectroscopy to re-measure the branching ratios reported by Moore et al. The new results confirm and extend those of Moore et al. Huang et al. identified three product channels: (a) 2 Cl + O<sub>2</sub>, (b) 2 ClO, and (c) ClO + Cl + O. The branching ratios among these product channels are 0.82, 0.08, and 0.10 at 248.4 nm, and 0.81, 0.19, and 0.00 at 308.4 nm. These results suggest that the branching ratio of channel-a is only weakly dependent on  $\lambda$  and that of channel-c arises from fragmentation of highly excited ClO radicals; at longer wavelengths, there is not enough available energy to break the bond.

*Recommendations:* Quantum yield of channel-a  $\Phi_a = 0.8 (\pm 0.1)$  at all  $\lambda$ ;  $\Phi_b + \Phi_c = 0.2 (\pm 0.1)$  at all  $\lambda$ ;  $\Phi_c = 0.0 (\pm 0.1)$  at  $\lambda > 300 \text{ nm}$ . Additional determinations of photolysis quantum yields and product branching ratios at wavelengths longer than 300 nm would be desirable.

*Theoretical Studies:* Toniolo et al.,<sup>29</sup> Peterson and Francisco,<sup>23</sup> and Matus et al.<sup>14</sup> report theoretical calculations for the electronic transitions of the ClOOCl UV absorption spectrum that include transitions to excited singlet and triplet states. Peterson and Francisco report that the strongest triplet transition is dissociative to Cl + ClOO, centered near 385 nm, and is three orders of magnitude weaker than the strongest

singlet transition at shorter wavelengths. Kaledin and Morokuma<sup>12</sup> studied the ClOOCl photodissociation dynamics and predict the synchronous and sequential formation of 2 Cl + O<sub>2</sub> at 308 nm, and three possible fragmentation routes at 248 nm: 2Cl + O<sub>2</sub>, Cl + O(<sup>3</sup>P) + ClO, and 2 Cl + 2O(<sup>3</sup>P). Similar theoretical calculations performed by Toniolo et al.<sup>28</sup> for excitation at 264, 325, and 406 nm found that 2Cl + O<sub>2</sub> was produced at all wavelengths with only a small yield of 2 ClO at the shortest wavelength.

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of chloryl chloride, ClClO<sub>2</sub>, has been measured in the gas-phase at room temperature and in a noble gas matrix at low temperature by Müller and Willner<sup>2</sup> (220–390 nm). In another study from the same group, Jacobs et al.<sup>1</sup> (180–390 nm) re-investigated the spectrum. The spectrum has two overlapping absorption bands with maxima at 226 nm ( $\sigma = 1.38 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ ) and 296 nm ( $\sigma = 1.51 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ ). The recommended absorption cross sections in Table 4F-12 are taken from Müller and Willner.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* Photolysis of matrix isolated ClClO<sub>2</sub> suggests that it absorbs in the visible between 500 and 800 nm with cross sections estimated to be  $< 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ .

**Table 4F-12. Recommended Absorption Cross Sections of ClClO<sub>2</sub> at 298 K**

## F9. **Cl<sub>2</sub>O<sub>3</sub> (dichlorine trioxide, chlorine chlorate)**

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption spectrum of Cl<sub>2</sub>O<sub>3</sub> (dichlorine trioxide, chlorine sesquioxide, chlorine chlorate) has been measured by Lipscomb et al.<sup>5</sup> (257.7 nm) at 293 K, Hayman and Cox<sup>4</sup> (220–335 nm) at 233 K, Burkholder et al.<sup>1</sup> (220–320 nm) in the range 200–260 K, Harwood et al.<sup>3</sup> (220–330 nm) at 223 K, and Green et al.<sup>2</sup> (201–320 nm) at 243 K. The spectrum has a strong band centered near 265 nm and evidence for another band at shorter wavelengths. Overall, the agreement among the various studies in terms of the absolute absorption cross sections and the wavelength dependence of the spectrum is poor. Hayman and Cox<sup>3</sup> report the largest peak absorption cross section and Green et al.<sup>2</sup> report the lowest, ~30% lower.

The spectra from Green et al.<sup>2</sup> and Burkholder et al.<sup>1</sup> are in reasonable agreement and have significantly lower cross sections in the long wavelength region than reported by Harwood et al.<sup>3</sup> and Hayman and Cox.<sup>4</sup> The recommended absorption cross sections in Table 4F-13 were obtained by averaging the cross section data from Hayman and Cox,<sup>4</sup> Burkholder et al.,<sup>1</sup> Harwood et al.,<sup>3</sup> and Green et al.<sup>2</sup> Uncertainty factors of 1.5 (2 $\sigma$ ) for  $\lambda < 300$  nm and 2 (2 $\sigma$ ) for  $\lambda > 300$  nm are estimated due primarily to the large spread in the available cross section studies.

*Photolysis Quantum Yield and Product Studies:* Absorption in the UV is expected to lead to unit photodissociation.

**Table 4F-13. Recommended Absorption Cross Sections of Cl<sub>2</sub>O<sub>3</sub> at 220–260 K**

#### F10. Cl<sub>2</sub>O<sub>4</sub> (dichlorine tetraoxide, chlorine perchlorate)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of Cl<sub>2</sub>O<sub>4</sub> (dichlorine tetraoxide, chlorine perchlorate) has been measured at room temperature by Lopez and Sicre<sup>2</sup> (200–310 nm) and Green et al.<sup>1</sup> (200–350 nm). The absorption spectrum has a weak band between 303 and 350 nm with a maximum at 327 nm, a stronger band between 212 and 303 nm with a maximum at 233 nm, and a further increase in cross section below 212 nm. The absorption cross sections reported by Lopez and Sicre<sup>2</sup> and Green et al.,<sup>1</sup> who applied similar methods of preparing Cl<sub>2</sub>O<sub>4</sub>, are in good agreement in the region ~215–250 nm.

Discrepancies in the cross section data are apparent below 215 nm, where the values of Lopez and Sicre<sup>2</sup> are larger by as much as a factor ~1.7 at 200 nm and at wavelengths >260 nm. The recommended absorption cross sections in Table 4F-14 are from Green et al.,<sup>1</sup> which is thought to be the more accurate measurement.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F11. Cl<sub>2</sub>O<sub>6</sub> (dichlorine hexoxide)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of dichlorine hexoxide, Cl<sub>2</sub>O<sub>6</sub>, has been measured at room temperature by Lopez and Sicre<sup>4</sup> (200–386 nm), Jansen et al.<sup>3</sup> (268 nm), and Green et al.<sup>2</sup> (200–450 nm). The spectrum reported by Goodeve and Richardson<sup>1</sup> and attributed to ClO<sub>3</sub> was shown by Lopez and Sicre<sup>4</sup> to most likely be that of Cl<sub>2</sub>O<sub>6</sub>. The cross sections measured by Lopez and Sicre<sup>4</sup> are several times larger than those reported by Goodeve and Richardson<sup>1</sup> but the shape of the spectrum is similar. There is excellent agreement between the data of Lopez and Sicre<sup>4</sup> and Green et al.<sup>2</sup> at wavelengths between 210 and 310 nm. At 200 nm the data from Green et al.<sup>2</sup> are smaller by ~10% than those of Lopez and Sicre.<sup>4</sup> At longer wavelengths the Green et al.<sup>2</sup> cross section data are larger with the difference increasing with increasing wavelength up to a factor ~3 at 380 nm. The recommended absorption cross sections in Table 4F-15 are taken from Green et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F12. Cl<sub>2</sub>O<sub>7</sub> (dichlorine heptoxide)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of dichlorine heptoxide, Cl<sub>2</sub>O<sub>7</sub>, has been measured at room temperature by Goodeve and Windsor<sup>1</sup> (222–302 nm) and Lin<sup>2</sup> (180–310 nm). Although both studies report a spectrum with monotonically decreasing absorption cross sections with increasing wavelength, there is poor agreement between the two data sets. The cross sections reported by Goodeve and Windsor<sup>1</sup> are larger at wavelengths <290 nm than those reported by Lin<sup>2</sup> with a difference of a factor of 4 at 225 nm. At wavelengths >290 nm, the cross sections reported by Goodeve and Windsor<sup>1</sup> are smaller than those of Lin.<sup>2</sup> The recommended absorption cross sections in Table 4F-16 are taken from Lin.<sup>2</sup>

**Photolysis Quantum Yield and Product Studies:** No recommendation.

**F13. HCl (hydrogen chloride)**[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of hydrogen chloride, HCl, has been measured at room temperature by Romand and Vodar<sup>18</sup> (139–207 nm), Romand<sup>17</sup> (139–207 nm), Myer and Samson<sup>13</sup> (140–200 nm), Inn<sup>6</sup> (140–220 nm), Roxlo and Mandl<sup>19</sup> (170–215 nm), Nee et al.<sup>14</sup> (132–185 nm), Bahou et al.<sup>2</sup> (120–230 nm), Cheng et al.<sup>3</sup> (120–230 nm), Vatsa and Volpp<sup>21</sup> (121.6 nm), Mo et al.<sup>12</sup> (193 nm), and Hanf et al.<sup>5</sup> (135 nm). Bahou et al.<sup>2</sup> (120–230 nm) and Cheng et al.<sup>3</sup> (120–230 nm) have also measured the absorption spectrum of DCI. VUV absorption cross sections have been obtained by dipole (e,e) spectroscopy in the region 8–40 eV (155–31 nm) by Daviel et al.<sup>4</sup> The absorption spectrum has a broad absorption band between 135 and 230 nm, corresponding to the A  $^1\Pi \leftarrow X ^1\Sigma^+$  transition, with the maximum at  $\sim$ 154 nm for HCl and  $\sim$ 156 nm for DCI. There is good agreement among the data of Bahou et al.,<sup>2</sup> Cheng et al.,<sup>3</sup> with the data from Nee et al.<sup>14</sup> and Inn.<sup>6</sup> The cross sections of Bahou et al.<sup>2</sup> and Cheng et al.<sup>3</sup> are in general larger than those of Nee et al.<sup>14</sup> by  $<10\%$  in the region 132–170 nm and by  $<25\%$  at wavelengths  $>170$  nm. In addition, the cross sections of Bahou et al.<sup>2</sup> and Cheng et al.<sup>3</sup> are slightly smaller, by  $<10\%$ , than those of Inn<sup>6</sup> except for the region  $>210$  nm. The absorption spectrum of Inn<sup>6</sup> has shoulders near 147.5 nm and 160 nm around the maximum at  $\sim$ 155 nm. This is in contrast to the results of Bahou et al.<sup>2</sup> and Cheng et al.<sup>3</sup> (0.1 nm resolution) and those of Nee et al.<sup>14</sup> (0.05 nm resolution). The recommended absorption cross sections for HCl and DCI in Table 4F-17 are averages over 2.5 nm and 5 nm intervals of the data from Bahou et al.<sup>2</sup> An uncertainty factor of 1.1 ( $2\sigma$ ) is estimated for  $180 < \lambda < 230$  nm.

*Photolysis Quantum Yield and Product Studies:* Photodissociation of HCl was studied by Matsumi et al.<sup>9–11</sup> and Tonokura et al.,<sup>20</sup> and the branching fraction Cl ( $^2\text{P}_{1/2}$ ) / (Cl ( $^2\text{P}_{1/2}$ ) + Cl ( $^2\text{P}_{3/2}$ )) was determined to be  $0.33 \pm 0.05$  at 193 nm and  $0.45–0.47 (\pm 0.04)$  at 157 nm. Lambert et al.<sup>7</sup> measured branching fractions between 0.47 and 0.33 for eight wavelengths between 193 and 235 nm for HCl. Zhang et al.<sup>22</sup> obtained  $0.41 \pm 0.01$  at 193.3 nm. Regan et al.<sup>16</sup> obtained values between 0.42 and 0.48 for 5 wavelengths in the range 201–210 nm, and Regan et al.<sup>15</sup> report values between 0.41 to 0.53 for selected ro-vibrational states at 235 nm. The results from Lambert et al.,<sup>7</sup> Zhang et al.,<sup>22</sup> Regan et al.,<sup>15,16</sup> and Liyanage et al.<sup>8</sup> are in good agreement with the calculations of Alexander et al.<sup>1</sup>

#### F14. HOCl (hypochlorous acid)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV/vis absorption spectrum of hypochlorous acid, HOCl, has an intensive singlet-singlet absorption in the near-UV with a maximum near 240 nm due mostly to the 2 <sup>1</sup>A' ← 1 <sup>1</sup>A' transition and a weaker band arising from the 1 <sup>1</sup>A'' ← 1 <sup>1</sup>A' transition that appears as a shoulder near 300 nm. The absorption cross sections of HOCl vapor have been reported by several groups. Molina and Molina<sup>10</sup> and Knauth et al.<sup>7</sup> produced HOCl using equilibrium mixtures with Cl<sub>2</sub>O and H<sub>2</sub>O. Mishalanie et al.<sup>9</sup> and Permien et al.<sup>12</sup> used a dynamic source to generate the HOCl vapor. The cross section values reported by Molina and Molina,<sup>10</sup> Mishalanie et al.,<sup>9</sup> and Permien et al.<sup>12</sup> are in reasonable agreement between 250 and 330 nm. In this wavelength range, the cross section values reported by Knauth et al.<sup>7</sup> are significantly smaller, e.g. a factor of 4 at 280 nm. At wavelengths >340 nm, the cross sections from Mishalanie et al. are significantly smaller than those obtained by the other three groups with a difference of an order of magnitude at 365 nm.

Burkholder<sup>3</sup> (200–380 nm) measured the HOCl absorption spectrum following photolysis of equilibrium mixtures of Cl<sub>2</sub>O–H<sub>2</sub>O–HOCl. The HOCl spectrum obtained has two absorption maxima with peaks at 242 and 304 nm in excellent agreement with the work of Knauth et al.<sup>7</sup> The agreement with the spectra reported by Molina and Molina,<sup>10</sup> Mishalanie et al.,<sup>9</sup> and Permien et al.<sup>12</sup> is poor. The discrepancies can most likely be attributed to the methods and uncertainties associated with correcting measured absorption spectra for the presence of Cl<sub>2</sub> and Cl<sub>2</sub>O. In the study by Burkholder,<sup>3</sup> several control experiments were carried out in order to check the internal consistency of the data. Barnes et al.<sup>1</sup> examined the near UV HOCl spectrum by monitoring the OH fragments resulting from photodissociation and observed a weak band centered at 387 nm that extends to 480 nm. This transition arises from a weak singlet-triplet transition (Minaev<sup>8</sup>). The recommended cross sections in Table 4F-18 are calculated from an analytical expression provided by Barnes et al.<sup>1</sup> that was based on the cross section values from Burkholder<sup>3</sup> and Barnes et al.<sup>1</sup> The HOCl spectrum reported by Jungkamp et al.<sup>6</sup> is in excellent agreement with this recommendation for wavelengths <350 nm but deviates significantly at longer wavelengths. Uncertainty factors of 1.1 (2σ) and 1.2 (2σ) are estimated for the wavelength regions  $\lambda \leq 350$  nm and  $\lambda > 350$  nm, respectively.

*Photolysis Quantum Yield and Product Studies:* Molina et al.<sup>11</sup> observed production of OH radicals in the laser photolysis of HOCl around 310 nm. Butler and Phillips<sup>4</sup> found no evidence for O atom production following HOCl photolysis at 308 nm and reported an upper limit for the primary quantum yield for the HCl + O channel of ~0.02. Vogt and Schindler<sup>14</sup> used broadband photolysis in the 290–390 nm wavelength range and report Φ(OH) to be >0.95. Schindler et al.<sup>13</sup> measured Φ(Cl) to be  $1.00 \pm 0.05$  at 308 nm. These authors also determined the probability, P, for production of Cl\*(<sup>2</sup>P<sub>1/2</sub>) relative to Cl (<sup>2</sup>P<sub>3/2</sub>) to be  $0.035 \pm 0.02$  at 308 nm, and  $0.35 \pm 0.02$  at 235 nm. These values are in agreement with the value of  $0.30 \pm 0.07$  at 236 nm.

reported by Bell et al.<sup>2</sup> Fujiwara and Ishiwata<sup>5</sup> determined the relative yield of OH( $^2\Pi_{3/2}$ ) / OH( $^2\Pi_{1/2}$ ) to be 2.0 at 266 nm and 1.5 at 355 nm. A unit quantum yield for the OH + Cl channel is recommended.

**Table 4F-18. Recommended Absorption Cross Sections of HOCl at 298 K**

## F15. ClNO (nitrosyl chloride)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Nitrosyl chloride, ClNO, has a continuous UV/vis absorption spectrum extending beyond 650 nm. There is good agreement between the work of Martin and Gareis<sup>6</sup> (235–400 nm), Ballash and Armstrong<sup>1</sup> (185–540 nm), Illies and Takacs<sup>5</sup> (190–400 nm), and Tyndall et al.<sup>9</sup> (190–350 nm) except around 230 nm where the values of Ballash and Armstrong are larger by almost a factor of two. Roehl et al.<sup>7</sup> (350–650 nm) measured ClNO absorption cross sections at several temperatures between 223 and 343 K. Their room temperature results agree to within 15% with those of Martin and Gareis,<sup>6</sup> Ballash and Armstrong,<sup>1</sup> and Tyndall et al.<sup>9</sup> The recommended absorption cross sections in Table 4F-19 are taken from the work of Tyndall et al.<sup>9</sup> between 190 and 350 nm and from Roehl et al.<sup>7</sup> beyond 350 nm.

*Photolysis Quantum Yield and Product Studies:* The quantum yield for the primary photolytic process has been reviewed by Calvert and Pitts.<sup>2</sup> The quantum yield is unity over the entire visible and near-ultraviolet bands. Chichinin<sup>3</sup> found evidence of ground state ( $^2P_{3/2}$ ) and excited ( $^2P_{1/2}$ ) atomic chlorine products and measured a relative quantum yield  $Cl(^2P_{1/2}) / (Cl(^2P_{1/2}) + Cl(^2P_{3/2}))$  to be  $0.88 \pm 0.12$  at 248 nm and  $0.90 \pm 0.10$  at 351 nm. Felder and Morley<sup>4</sup> obtained 0.80 at 248 nm and Skorokhodov et al.<sup>8</sup> obtained  $0.48 \pm 0.03$  at 212 nm, 0.30 at 235 nm, and  $0.52 \pm 0.03$  at 248 nm.

**Table 4F-19. Recommended Absorption Cross Sections of ClNO at 298 K**

$\lambda$ (nm)	$10^{20}\sigma$ (cm <sup>2</sup> )

**F16. ClNO<sub>2</sub> (nitryl chloride)**
[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption spectrum of nitryl chloride, ClNO<sub>2</sub>, has been measured at room temperature by Martin and Gareis<sup>6</sup> (230–330 nm), Illies and Takacs<sup>5</sup> (185–400 nm), Nelson and Johnston<sup>7</sup> (270–370 nm), Ganske et al.<sup>3</sup> (200–370 nm), Furlan et al.<sup>2</sup> (190–450 nm), and Ghosh et al.<sup>4</sup> (200–475 nm). The absorption spectrum has three broad overlapping bands, a weak band at ~300 nm and two stronger bands at ~215 nm and below 185 nm. In the range 220–280 nm, weak but distinct vibrational structure was observed by Furlan et al.<sup>2</sup> A major source of discrepancies in the data results from the presence of impurities. The recommended absorption cross sections in Table 4F-20 are taken from Ghosh et al. (rounded to 3 significant figures).

Ghosh et al. measured the ClNO<sub>2</sub> UV/vis spectrum temperature dependence over the range 210–296 K (the only temperature dependent study available). They parameterized the spectrum temperature dependence using the empirical formula:

$$\sigma(\lambda, T) = \sigma(\lambda, 296 \text{ K}) \times (1 + A(\lambda) \times (T - 296) + B(\lambda) \times (T - 296)^2)$$

The recommended fit parameters are included in Table 4F-20.

*Photolysis Quantum Yield and Product Studies:* Nelson and Johnston<sup>7</sup> report a value of  $0.93 \pm 0.15$  for  $\Phi(\text{Cl})$  and  $\Phi(\text{O}) < 0.02$  for photolysis at 350 nm. Carter et al.<sup>1</sup> reported the formation of NO<sub>2</sub> in the electronic ground state (yield  $0.15 \pm 0.05$ ) and in the excited state (yield  $0.85 \pm 0.05$ ) for 235 nm photolysis. Ghosh et al.<sup>4</sup> report  $\Phi(\text{O})$  values of  $0.67 \pm 0.12$  and  $0.15 \pm 0.03$  ( $2\sigma$ ) for photolysis at 193 and 248 nm, respectively.

## F17. ClONO (chlorine nitrite)

[Back to Index](#)

(Recommendation: 78, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of chlorine nitrite, ClONO, was measured by Molina and Molina.<sup>1</sup> The absorption cross sections were determined by mass balance during the Cl<sub>2</sub>O + ClNO → Cl<sub>2</sub> + ClONO reaction and isomerization of ClONO to ClNO<sub>2</sub>. The recommended absorption cross sections in Table 4F-21 are taken from this study.

*Photolysis Quantum Yield and Product Studies:* It is assumed that the quantum yield for ClONO UV photolysis is unity. The Cl–O bond strength is only ~20 kcal mole<sup>-1</sup>, so that chlorine atoms are likely photolysis products.

## F18. ClONO<sub>2</sub> (chlorine nitrate)

[Back to Index](#)

ClONO <sub>2</sub> + hν	→ Cl + NO <sub>3</sub>	173 kJ mol <sup>-1</sup>	692 nm	(1)
	→ ClO + NO <sub>2</sub>	113 kJ mol <sup>-1</sup>	1063 nm	(2)
	→ O( <sup>3</sup> P) + ClONO	291 kJ mol <sup>-1</sup>	412 nm	(3)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The recommended cross sections of chlorine nitrate, ClONO<sub>2</sub>, are taken from the work of Burkholder et al. (196–432 nm, 220–296 K).<sup>2</sup> The cross section values are listed in Table 4F-22 together with the parameters needed to compute their temperature dependence. These values are in good agreement with those reported by Molina and Molina,<sup>10</sup> which provided the basis for earlier recommendations and which supersedes the work of Rowland et al.<sup>15</sup> An uncertainty factor in the room temperature cross sections of 1.1 (2σ) is estimated for the wavelength region 196 < λ < 432 nm.

*Photolysis Quantum Yield and Product Studies:* Several groups have investigated the identity of the primary photolytic fragments. Smith et al.<sup>16</sup> report O + ClONO as the most likely products, using end-product analysis and steady-state photolysis. The results of Chang et al.,<sup>4</sup> which were obtained using the very low-pressure photolysis (VLPPh) technique, indicate that the products are Cl + NO<sub>3</sub>, with a quantum yield of 1.0 ± 0.2. Adler-Golden and Wiesenfeld,<sup>1</sup> using a flash photolysis atomic absorption technique, find O atoms to be the predominant photolysis product and report a quantum yield for Cl atom production of less than 4%. Marinelli and Johnston<sup>8</sup> report a quantum yield for NO<sub>3</sub> production at 249 nm between 0.45 and 0.85, with a most likely value of 0.55; they monitored NO<sub>3</sub> by tunable dye laser absorption at 662 nm. Margitan<sup>7</sup> used atomic resonance fluorescence detection of O and Cl atoms and found the quantum yield at 266 nm and at 355 nm to be 0.9 ± 0.1 for Cl atom production and ~0.1 for O atom production, with no discernible difference at the two wavelengths. These results were confirmed by Knauth and Schindler,<sup>6</sup> who used end-product analysis to infer the quantum yields from photolysis studies at 265 and 313 nm. Burrows et al.<sup>3</sup> report also Cl and NO<sub>3</sub> as the photolysis products at 254 nm, with a quantum yield of unity within experimental error, and an O atom quantum yield of 0.24. In contrast, Nikolaisen et al.<sup>13</sup> using broadband photolysis found that at λ > 200 nm the relative branching ratios are 0.61 ± 0.20 for the channel ClO + NO<sub>2</sub> and 0.39 ± 0.20 for the channel Cl + NO<sub>3</sub>; in the λ > 300 nm region the quantum yields are found to be 0.44 ± 0.08 for production of ClO and NO<sub>2</sub> and 0.56 ± 0.08 for production of Cl and NO<sub>3</sub>. Minton et al.,<sup>9</sup> Nelson et al.,<sup>12</sup> and Moore et al.<sup>11</sup> made the first direct measurements of ClO and obtained comparable yields for the Cl + NO<sub>3</sub> and the ClO + NO<sub>2</sub> channels, using a molecular beam technique: at 193 nm they obtained respectively 0.64 ± 0.08 and 0.36 ± 0.08, at 248 nm 0.54 ± 0.08 and 0.46 ± 0.08, and at 308 nm 0.67 ± 0.06 and 0.33 ± 0.06. These authors found no evidence for the O + ClONO channel and placed an upper limit for this channel of 0.04. Tyndall et al.<sup>17</sup> observed quantum yields of 0.80 ± 0.08 and 0.28 ± 0.12 for Cl and ClO at 308 nm using resonance fluorescence detection methods and reported a O(<sup>3</sup>P) yield of ≤0.05. Ravishankara,<sup>14</sup> Goldfarb et al.,<sup>5</sup> and Yokelson et al.<sup>18</sup> have studied the photodissociation of ClONO<sub>2</sub> at 193, 222, 248 and 308 nm using atomic resonance fluorescence and time resolved absorption methods. They found that Cl and ClO are the two major dissociation products at 222, 248 and 308 nm, whereas at 193 nm, the quantum yield of O atoms was larger than the yield of ClO. At 193, 222, 248 and 308 nm, the yield of Cl was 0.53 ± 0.10, 0.46 ± 0.10, 0.41 ± 0.13 and 0.64 ± 0.20, respectively; the O atom yield 0.73 ± 0.08, 0.17 ± 0.08, <0.10 and <0.05; and the ClO yield 0.29 ± 0.20, 0.64 ± 0.20, 0.39 ± 0.19 and 0.37 ± 0.19. The NO<sub>3</sub> yield was determined by Yokelson et al.<sup>18</sup> to be 0.93 ± 0.24 at 352.5 nm, 0.67 ± 0.09 at 308 nm, 0.60 ± 0.09 at 248 nm, and 0.18 ± 0.04 at 193 nm. In addition, Yokelson et al.<sup>18</sup> measured the Cl atom yield as 0.73 ± 0.14 at 308 nm, 0.60 ± 0.12 at 248 nm and 0.45 ± 0.08 at 193 nm, and the O atom yield as <0.4 at 248 nm and <0.9 at 193 nm. Zou et al.<sup>19</sup> determined absolute quantum yields for the Cl and ClO channels at 235 nm to be 0.42 ± 0.1 and 0.58 ± 0.1, respectively, using molecular beam techniques and TOFMS/REMPI.

The recommended quantum yield values for production of Cl + NO<sub>3</sub> ( $\Phi_1$ ) and ClO + NO<sub>2</sub> ( $\Phi_2$ ) are given at the bottom of Table 4F-22 and are based on the work of Nelson et al.,<sup>12</sup> Moore et al.,<sup>11</sup> Nicklaisen et al.,<sup>13</sup> Goldfarb et al.,<sup>5</sup> and Yokelson et al.<sup>18</sup> For wavelengths shorter than 308 nm the value of  $\Phi_1$  is 0.6 and  $\Phi_2$  is 0.4. For longer wavelengths  $\Phi_1$  increases linearly to 0.9 at 350 nm with the corresponding decrease in  $\Phi_2$  to 0.1. There is no evidence for production of O + ClONO in the more recent work; the production of O atoms reported in some of the earlier studies may have resulted from the decomposition of excited NO<sub>3</sub>. Zou et al.<sup>19</sup> determined the quantum yield of spontaneous decomposition of NO<sub>3</sub> into NO<sub>2</sub> + O to be 0.20 and into NO + O<sub>2</sub> to be 0.006.

Work by Nickolaisen et al.<sup>13</sup> indicates that the photodissociation quantum yield is less than unity at wavelengths longer than ~330 nm because of the formation of a long-lived intermediate that may be quenched under atmospheric conditions (a situation analogous to that of Cl<sub>2</sub>O).

#### F19. CCl<sub>4</sub> (carbon tetrachloride)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of carbon tetrachloride, CCl<sub>4</sub>, has been measured at room temperature by Russell et al.<sup>15</sup> (110–200 nm), Causley and Russell<sup>2</sup> (110–200 nm), Gordus and Bernstein<sup>5</sup> (204–250 nm), Rowland and Molina<sup>13</sup> (186–226 nm), Roxlo and Mandl<sup>14</sup> (170–230 nm), Hubrich and Stuhl<sup>8</sup> (160–275 nm), Ibuki et al.<sup>9</sup> (105–210 nm), Hanf et al.<sup>6</sup> (135 and 193 nm), Currie et al.<sup>4</sup> (250 nm), Vanlaethem-Meurée et al.<sup>18</sup> (190–252 nm), Simon et al.<sup>17</sup> (174–250 nm), Prahlad and Kumar<sup>10</sup> (186–240 nm), and Rontu Carlon et al.<sup>12</sup> (184.95, 202.206, 206.200, 213.857, and 228.8 nm atomic lines and 200–235 nm). The room temperature data agree to within 10% between 190 and 235 nm and to within 20% and 40% at 240 and 250 nm, respectively (except the value at 250 nm reported by Currie et al.<sup>4</sup> that is significantly lower). The absorption spectrum of Prahlad and Kumar<sup>10</sup> has irregular structure over the entire wavelength range presumably due to the experimental precision of the measurements. In the range 180–186 nm, the cross section values reported by Hubrich and Stuhl<sup>8</sup> are higher by up to 25% than those reported by Simon et al.,<sup>17</sup> and the value at 186 nm reported by Prahlad and Kumar<sup>10</sup> is lower by 18% than the value of Simon et al. The value at 184.95 nm reported by Rontu Carlon et al. is in good agreement, to within 1.5%, with the JPL10-6 recommendation. At the maximum near 176 nm Hubrich and Stuhl<sup>8</sup> and Simon et al.<sup>17</sup> report an absorption cross section of  $1.01 \times 10^{-17} \text{ cm}^2$ . The peak cross section reported by Roxlo and Mandl<sup>14</sup> is lower,  $\sim 7 \times 10^{-18} \text{ cm}^2$ . Rebbert and Ausloos<sup>11</sup> derived a cross section at 313 nm of  $\leq 3.7 \times 10^{-26} \text{ cm}^2$  from the C<sub>2</sub>H<sub>5</sub>Cl yield in the photolysis of CCl<sub>4</sub>-C<sub>2</sub>H<sub>6</sub> mixtures.

The recommended room temperature absorption cross sections in Table 4F-23 are the mean of the values reported by Hubrich and Stuhl<sup>8</sup> and Simon et al.<sup>17</sup> in the region 174–192 nm, from Simon et al.<sup>17</sup> in the region 194–198 nm, and from the revised cross section parameterization reported by Rontu Carlon et al. (see below) for the  $200 \leq \lambda \leq 235$  nm region. Cross sections have been reported at longer wavelengths by Hubrich and Stuhl,<sup>8</sup> although no recommendation is given for this region. For the wavelength region 174–190 nm the estimated uncertainty factor is 1.2 (2σ) and for the region  $190 \leq \lambda \leq 235$  nm the estimated uncertainty factor is 1.06 (2σ).

The temperature dependence of the absorption spectrum has been measured by Currie et al.<sup>4</sup> (250 nm) over the range 297–477 K, Vanlaethem-Meurée et al.<sup>18</sup> (190–252 nm) at 279 and 296 K, Simon et al.<sup>17</sup> (174–250 nm) over the range 225–295 K, Prahlad and Kumar<sup>10</sup> (186–240 nm) over the range 220–300 K, and Rontu Carlon et al. (200–235 nm) over the range 210–350 K. The spectrum has a significant temperature dependence at wavelengths >205 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>17</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The parameters A<sub>n</sub> and B<sub>n</sub>, are valid for the temperature range 210–300 K and wavelength range 194–250 nm.

$A_0 = -37.104$	$B_0 = 1.0739$
$A_1 = -5.8218 \times 10^{-1}$	$B_1 = -1.6275 \times 10^{-2}$
$A_2 = 9.9974 \times 10^{-3}$	$B_2 = 8.8141 \times 10^{-5}$
$A_3 = -4.6765 \times 10^{-5}$	$B_3 = -1.9811 \times 10^{-7}$
$A_4 = 6.8501 \times 10^{-8}$	$B_4 = 1.5022 \times 10^{-10}$

On the basis of their results, Rontu Carlon et al. used the same empirical formula and reported a revised spectrum parameterization with the coefficients given below. The parameterization is valid for the wavelength range 200–235 nm and temperature range 210–350 K and reproduces their experimental data to within 3%. For the wavelength region 174–200 nm, Simon et al. report a temperature independent spectrum, which is inconsistent with the Rontu Carlon et al. results obtained at 185 and 200 nm. The Rontu Carlon et al. parameterization is recommended.

n	$A_n$	$B_n$
0	1112.736208	-1.116511649
1	-22.02146808	0.02447268904
2	0.1596666745	-0.0001954842393
3	-0.0005104078676	$6.775547148 \times 10^{-7}$
4	$6.062440506 \times 10^{-7}$	$-8.621070147 \times 10^{-10}$

The VUV absorption spectrum of  $\text{CCl}_4$  has been measured by Russell et al.<sup>15</sup> (112–175 nm), Causley and Russell<sup>2</sup> (111–195 nm), Ibuki et al.<sup>9</sup> (105–210 nm), Ho<sup>7</sup> (4.9–200 nm), and Seccombe et al.<sup>16</sup> (50–200 nm). Burton et al.<sup>1</sup> measured cross sections for the region 6.4–225 nm using dipole (e,e) spectroscopy. The agreement in the  $\sigma(\text{Lyman-}\alpha, 298 \text{ K})$  values is to within  $\sim 15\%$ . The recommended  $\sigma(\text{Lyman-}\alpha, 298 \text{ K})$  is the average of the interpolated results from Causley and Russell, Ibuki et al., and Ho,  $3.7 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ , with an uncertainty factor of 1.2 ( $2\sigma$ ).

*Photolysis Quantum Yield and Product Studies:* Quantum yields  $\geq 0.9$  and  $\sim 0.75$  for the photodissociative processes  $\text{CCl}_4 + h\nu \rightarrow \text{CCl}_3 + \text{Cl}$  at 213.9 nm and  $\text{CCl}_4 + h\nu \rightarrow \text{CCl}_2 + 2\text{Cl}$  at 163.3 nm, respectively, were derived from the gas-phase photolysis of  $\text{CCl}_4$  in the presence of  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{C}_2\text{H}_6$  by Rebbert and Ausloos.<sup>11</sup> Clark and Husain<sup>3</sup> report a quantum yield for  $\text{Cl}^*(^2\text{P}_{1/2})$  atom formation in the broadband photolysis of  $\text{CCl}_4$  to be  $0.78 \pm 0.27$ . Hanf et al.<sup>6</sup> reported Cl atom quantum yields in the photolysis of  $\text{CCl}_4$  to be  $\Phi(\text{Cl}) = 1.1 \pm 0.05$  and  $\Phi(\text{Cl}^*) = 0.4 \pm 0.02$  (thus  $\Phi(\text{Cl} + \text{Cl}^*) = 1.5 \pm 0.1$ ) at 193 nm and  $\Phi(\text{Cl}) = 1.5 \pm 0.07$  and  $\Phi(\text{Cl}^*) = 0.4 \pm 0.02$  (thus  $\Phi(\text{Cl} + \text{Cl}^*) = 1.9 \pm 0.1$ ) at 135 nm. A quantum yield of unity with  $\Phi(\text{Cl}) = 1$  is recommended.

**Table 4F-23. Recommended Absorption Cross Sections of  $\text{CCl}_4$  at 295 K**

$\lambda$ (nm)	$10^{20} \sigma$ ( $\text{cm}^2$ )	$\lambda$ (nm)	$10^{20} \sigma$ ( $\text{cm}^2$ )

## F20. CH<sub>3</sub>OCl (methyl hypochlorite)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV/vis absorption spectrum of methyl hypochlorite, CH<sub>3</sub>OCl, has been measured by Crowley et al.<sup>1</sup> (200–460 nm) and Jungkamp et al.<sup>2</sup> (230–400 nm). The spectrum has overlapping absorption bands with maxima at 230 and 310 nm. The agreement between the two data sets is good at wavelengths longer than 250 nm. At the maximum near 230 nm the cross sections from Jungkamp et al.<sup>2</sup> are about 15% smaller. The recommended cross sections in Table 4F-24 are the mean of the values reported by these two groups.

**Photolysis Quantum Yield and Product Studies:** Schindler et al.<sup>4</sup> measured the quantum yield for the product channel Cl + CH<sub>3</sub>O to be 0.95 ± 0.05 at 308 nm. They also determined an upper limit of <0.01 for HCl formation at 248 nm and the ratio Cl\*( $2^2P_{1/2}$ )/Cl( $2^2P_{3/2}$ ) following photolysis at 235 and 238 nm to be 1.45 ±

0.05. Krisch et al.<sup>3</sup> used photofragment translational spectroscopy to confirm that photodissociation of CH<sub>3</sub>OCl at 248 nm resulted in only the cleavage of the O-Cl bond and the formation of Cl and CH<sub>3</sub>O.

**Table 4F-24. Recommended Absorption Cross Sections of CH<sub>3</sub>OCl at 295 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )	$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )	$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of CHCl<sub>3</sub> (trichloromethane, chloroform) has been measured at room temperature by Lucazeau and Sandorfy<sup>5</sup> (113–182 nm), Brownsword et al.<sup>2</sup> (Lyman-α, 121.6 nm), Russell et al.<sup>6</sup> (110–200 nm), Gordus and Bernstein<sup>3</sup> (222.7 nm), Hubrich and Stuhl<sup>4</sup> (160–255 nm), Vanlaethem-Meurée et al.<sup>8</sup> (190–230 nm), and Simon et al.<sup>7</sup> (174–240 nm). The room temperature cross sections from Vanlaethem-Meurée et al.<sup>8</sup> and Simon et al.<sup>7</sup> are nearly identical in the wavelength region 190–210 nm. Differences of ~15% exist at longer wavelengths. The data of Hubrich and Stuhl<sup>4</sup> and Simon et al.<sup>7</sup> agree to within 10% between 180 and 234 nm. Differences of ~25% exist in the long wavelength tail with the values of Hubrich and Stuhl<sup>4</sup> being larger. In the region of the absorption maximum at ~176 nm, the spread in the reported cross section values is the largest. Simon et al.<sup>7</sup> report  $\sigma(176 \text{ nm}) = \sim 5 \times 10^{-18} \text{ cm}^2$  compared to  $3.7 \times 10^{-18} \text{ cm}^2$  reported by Hubrich and Stuhl<sup>4</sup> and  $< 2 \times 10^{-18} \text{ cm}^2$  by Lucazeau and Sandorfy.<sup>5</sup> The recommended absorption cross sections in Table 4F-25 are only for wavelengths >180 nm and are the mean of the values reported by Hubrich and Stuhl<sup>4</sup> and Simon et al.<sup>7</sup> for the wavelength range 180–240 nm. For the wavelength range 242–256 nm the recommended cross sections are obtained by extrapolation,  $\log \sigma(\lambda) = -1.2277 - 0.0844 \lambda$ .

The temperature dependence of the absorption spectrum has been measured by Vanlaethem-Meurée et al.<sup>8</sup> (190–230 nm) at 279 and 296 K and Simon et al.<sup>7</sup> (174–240 nm) over the range 225–295 K. The temperature dependence is significant for wavelengths >194 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>7</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A<sub>n</sub> and B<sub>n</sub>, valid for the temperature range 210–300 K and wavelength range 190–240 nm, given below are recommended.

$A_0 = 269.80$	$B_0 = 3.7973$
$A_1 = -6.0908$	$B_1 = -7.0913 \times 10^{-2}$
$A_2 = 4.7830 \times 10^{-2}$	$B_2 = 4.9397 \times 10^{-4}$
$A_3 = -1.6427 \times 10^{-4}$	$B_3 = -1.5226 \times 10^{-6}$
$A_4 = 2.0682 \times 10^{-7}$	$B_4 = 1.7555 \times 10^{-9}$

*Photolysis Quantum Yield and Product Studies:* Quantum yields for H atom formation have been measured by Brownsword et al.<sup>1,2</sup> to be  $0.23 \pm 0.03$  and  $0.13$  at 121.6 and 157.6 nm, respectively. H atom formation was not detected in the photolysis at 193.3 nm.

## F22. CH<sub>2</sub>Cl<sub>2</sub> (dichloromethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of dichloromethane, CH<sub>2</sub>Cl<sub>2</sub>, has been measured at room temperature by Russell et al.<sup>5</sup> (110–200 nm), Brownsword et al.<sup>2</sup> (Lyman- $\alpha$ , 121.6 nm), Gordus and Bernstein<sup>3</sup> (213 nm), Hubrich and Stuhl<sup>4</sup> (160–255 nm), Vanlaethem-Meurée et al.<sup>7</sup> (176–216 nm), and Simon et al.<sup>6</sup> (176–220 nm). The room temperature data of Vanlaethem-Meurée et al.<sup>7</sup> and Simon et al.<sup>6</sup> are nearly identical. The cross sections of Hubrich and Stuhl<sup>4</sup> are as much as 12% greater than those of Simon et al.<sup>6</sup> in the 176–206 nm wavelength range. Differences of ~50% exist in the 185–220 nm range. The recommended absorption cross sections in Table 4F-26 are the mean of the values reported by Hubrich and Stuhl<sup>4</sup> and Simon et al.<sup>6</sup> for the wavelength range 176–220 nm. For wavelengths >220 nm the recommended cross sections are obtained by extrapolation,  $\log \sigma(\lambda) = -2.1337 - 0.08439 \lambda$ . The measured cross section values in this wavelength range from Hubrich and Stuhl<sup>4</sup> are smaller by ~7% for wavelengths <230 nm and larger ~50% between 235 and 255 nm than the extrapolated values.

The temperature dependence of the absorption spectrum has been measured by Vanlaethem-Meurée et al.<sup>7</sup> (176–216 nm) at 279 and 296 K and Simon et al.<sup>6</sup> (176–220 nm) over the range 225–295 K. The temperature dependence is significant for wavelengths >190 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>6</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A<sub>n</sub> and B<sub>n</sub>, valid for the temperature range 210–300 K and wavelength range 176–220 nm, given below are recommended.

A <sub>0</sub> = -1431.8	B <sub>0</sub> = -3.1171
A <sub>1</sub> = 27.395	B <sub>1</sub> = 6.7874 × 10 <sup>-2</sup>
A <sub>2</sub> = -1.9807 × 10 <sup>-1</sup>	B <sub>2</sub> = -5.5000 × 10 <sup>-4</sup>
A <sub>3</sub> = 6.3468 × 10 <sup>-4</sup>	B <sub>3</sub> = 1.9649 × 10 <sup>-6</sup>
A <sub>4</sub> = -7.6298 × 10 <sup>-7</sup>	B <sub>4</sub> = -2.6101 × 10 <sup>-9</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for H atom formation have been measured by Brownsword et al.<sup>1,2</sup> to be 0.28 ± 0.03, 0.23, and 0.002 ± 0.001 at 121.6, 157.6, and 193.3 nm, respectively.

**F23. CH<sub>3</sub>Cl (chloromethane, methyl chloride)**[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of CH<sub>3</sub>Cl (chloromethane, methyl chloride) has been measured at room temperature by Russell et al.<sup>6</sup> (110–200 nm), Brownsword et al.<sup>2</sup> (Lyman- $\alpha$ , 121.6 nm), Felps et al.<sup>3</sup> (171.2 nm), Robbins<sup>5</sup> (174–220 nm), Hubrich et al.<sup>4</sup> (158–235 nm), Vanlaethem-Meurée et al.<sup>8</sup> (186–216 nm), and Simon et al.<sup>7</sup> (174–216 nm). The room temperature data generally agree within 10% over the wavelength range 174–216 nm and the data of Vanlaethem-Meurée et al.<sup>8</sup> and Simon et al.<sup>7</sup> are nearly identical. The cross section at 171 nm from Felps et al. is ~15% less than that of Hubrich et al.<sup>4</sup> The recommended absorption cross sections in Table 4F-27 are the mean of the values reported by Robbins,<sup>5</sup> Hubrich et al.,<sup>4</sup> and Simon et al.<sup>7</sup> in the range 174–184 nm, the mean of the values reported by Robbins,<sup>5</sup> Hubrich et al.,<sup>4</sup> Vanlaethem-Meurée et al.,<sup>8</sup> and Simon et al.<sup>7</sup> in the range 186–216 nm, and the mean of the values reported by Robbins<sup>5</sup> and Hubrich et al.<sup>4</sup> in the range 218–220 nm. For the wavelength range 222–236 nm the recommended values were obtained from a log-linear fit to the Hubrich et al.<sup>4</sup> data in the range 200–235 nm,  $\log \sigma(\lambda) = -0.24164 - 0.09743 \lambda$ . The cross section uncertainty in the 190–230 nm region is estimated to be 1.12 (2 $\sigma$ ), which encompasses the available data.

The VUV spectrum in the Lyman- $\alpha$  vicinity contains strong diffuse band structure with a maximum nearly coincident with Lyman- $\alpha$ . There is reasonable agreement, to within 30%, in the reported absorption cross sections. The recommended  $\sigma$ (Lyman- $\alpha$ ) is  $8.8 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  with an uncertainty factor of 1.15 (2 $\sigma$ ), which encompasses the available data.

The temperature dependence of the UV absorption spectrum has been measured by Hubrich et al.<sup>4</sup> (158–235 nm) at 208 and 298 K, Vanlaethem-Meurée et al.<sup>8</sup> (186–216 nm) at 255, 279, and 296 K, and Simon et al.<sup>7</sup> (174–216 nm) over the range 225–295 K. The temperature dependence of the absorption cross sections is significant at wavelengths above 194 nm where the cross sections decrease with decreasing temperature. There is very good agreement in the values reported by Vanlaethem-Meurée et al.<sup>8</sup> and Simon et al.<sup>7</sup> Simon et al.<sup>7</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters  $A_n$  and  $B_n$ , valid for the temperature range 210–300 K and wavelength range 174–216 nm, given below are recommended.

A <sub>0</sub> = -299.80	B <sub>0</sub> = -7.1727
A <sub>1</sub> = 5.1047	B <sub>1</sub> = 1.4837 × 10 <sup>-1</sup>
A <sub>2</sub> = -3.3630 × 10 <sup>-2</sup>	B <sub>2</sub> = -1.1463 × 10 <sup>-3</sup>
A <sub>3</sub> = 9.5805 × 10 <sup>-5</sup>	B <sub>3</sub> = 3.9188 × 10 <sup>-6</sup>
A <sub>4</sub> = -1.0135 × 10 <sup>-7</sup>	B <sub>4</sub> = -4.9994 × 10 <sup>-9</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for H atom formation have been measured by Brownsword et al.<sup>1,2</sup> to be  $0.53 \pm 0.05$ , 0.29, and  $0.012 \pm 0.006$  at 121.6, 157.6, and 193.3 nm, respectively.

#### F24. $\text{CH}_3\text{CCl}_3$ (1,1,1-trichloroethane, methylchloroform)

[Back to Index](#)

(1)

(Recommendation: 15–10, Note: 15–10, Evaluated: 15–10)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of  $\text{CH}_3\text{CCl}_3$  (1,1,1-trichloroethane, methylchloroform) has been measured at room temperature by Salomon et al.<sup>4</sup> (147 nm), Hubrich and Stuhl<sup>2</sup> (160–255 nm), Vanlaethem-Meurée et al.<sup>5</sup> (182–240 nm), and Nayak et al.<sup>3</sup> (160–240 nm). Hubrich and Stuhl<sup>2</sup> corrected their measured spectrum between 170 and 190 nm for the presence of a 1,4-dioxane stabilizer, corrections were <10.7%. Nayak et al.<sup>3</sup> also measured the absorption cross sections in the liquid-phase over the range 235–260 nm and used a wavelength shift procedure to derive the gas-phase cross section data in this wavelength range. The agreement of the room temperature data is within 20% in the region 165–205 nm. Between 210 and 240 nm, the data of Vanlaethem-Meurée et al.<sup>5</sup> and Nayak et al.<sup>3</sup> agree to within 15%, whereas the data from Hubrich and Stuhl<sup>2</sup> are 100–150% greater. The recommended absorption cross sections in Table 4F-28 are the mean of the values reported by Hubrich and Stuhl<sup>2</sup> and Nayak et al.<sup>3</sup> in the range 170–180 nm, the mean of the values reported by Vanlaethem-Meurée et al.,<sup>5</sup> Hubrich and Stuhl,<sup>2</sup> and Nayak et al.<sup>3</sup> in the range 185–205 nm, and the mean of the values reported by Vanlaethem-Meurée et al.<sup>5</sup> and Nayak et al.<sup>3</sup> in the range 210–240 nm. For wavelengths >240 nm, the recommended values were obtained by extrapolation of the Nayak et al.<sup>3</sup> data in the range 210–240 nm,  $\log \sigma(\lambda) = -1.59792 - 0.08066 \lambda$ . The values measured by Hubrich and Stuhl<sup>2</sup> in this wavelength range are greater by ~140% at 250 nm and less by ~80% at 255 nm than the recommended values. The cross section uncertainty in the 190–230 nm region is estimated to be 1.18 (2 $\sigma$ ), which encompasses the available data.

There are no Lyman- $\alpha$  cross section data available. A  $\sigma$ (Lyman- $\alpha$ ) value of  $7 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  is estimated with an uncertainty factor of 1.4 (2 $\sigma$ ).

The temperature dependence of the absorption spectrum has been measured by Vanlaethem-Meurée et al.<sup>5</sup> (182–240 nm) over the range 220–295 K and Nayak et al.<sup>3</sup> (160–240 nm) over the range 223–333 K. The temperature dependence of the absorption cross sections is significant at wavelengths >210 nm where the cross sections decrease with decreasing temperature. The studies of Nayak et al.<sup>3</sup> and Vanlaethem-Meurée et al.<sup>5</sup> are in good agreement. Vanlaethem-Meurée et al.<sup>5</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for  $T = 210, 230, 250, 270$ , and  $295 \text{ K}$ . The parameters  $A_n$  and  $B_n$ , valid for the temperature range 210–300 K and wavelength range 182–240 nm, reported by Gillotay and Simon<sup>1</sup> and given below are recommended.

$A_0 = 341.085191$	$B_0 = -1.660090$
$A_1 = -7.273362$	$B_1 = 3.079969 \times 10^{-2}$
$A_2 = 5.498387 \times 10^{-2}$	$B_2 = -2.106719 \times 10^{-4}$
$A_3 = -1.827552 \times 10^{-4}$	$B_3 = 6.264984 \times 10^{-7}$
$A_4 = 2.238640 \times 10^{-7}$	$B_4 = -6.781342 \times 10^{-10}$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## F29. $\text{CH}_2\text{Cl}(\text{CH}_2)_2\text{CH}_2\text{Cl}$ (1,4-dichlorobutane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of 1,4-dichlorobutane,  $\text{CH}_2\text{Cl}(\text{CH}_2)_2\text{CH}_2\text{Cl}$ , has been measured by Russell et al.<sup>1</sup> (129–188 nm). No recommendation is given.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Russell, B. R.; Edwards, L. O.; Raymonda, J. W. Vacuum ultraviolet absorption spectra of the chloromethanes. *J. Am. Chem. Soc.* **1973**, 95, 2129–2133, doi:10.1021/ja00788a008.

## F30. $\text{COCl}_2$ (carbonyl dichloride, phosgene)

[Back to Index](#)

$\text{COCl}_2 + \text{hv}$	$\rightarrow \text{CO} + \text{Cl}_2$	110 kJ mol <sup>-1</sup>	1084 nm	(1)
	$\rightarrow \text{ClCO} + \text{Cl}$	318 kJ mol <sup>-1</sup>	377 nm	(2)
	$\rightarrow \text{CO} + 2\text{Cl}$	353 kJ mol <sup>-1</sup>	339 nm	(3)
	$\rightarrow \text{CCl}_2 + \text{O}$	700 kJ mol <sup>-1</sup>	171 nm	(4)

(Recommendation: 94-26, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{COCl}_2$  (carbonyl dichloride, phosgene) has been measured at room temperature by Chou et al.<sup>2</sup> (185–226 nm), Okabe<sup>8</sup> (240–280 nm), Meller et al.<sup>7</sup> (200–315 nm), Jäger et al.<sup>6</sup> (172–220 nm), Okabe<sup>9,10</sup> (147, 184.9, and 253.7 nm), Glicker and Okabe<sup>4</sup> (229 and 254 nm), and Gillotay et al.<sup>3</sup> (166–308 nm). The spectrum shows a weak absorption band between 215 and 310 nm with the maximum at ~235 nm and a strong absorption band below 200 nm with the maximum at ~174 nm. The room temperature values reported in the various studies are in very good agreement, generally within 10%. An exception is in the region of the absorption minimum around 200 nm where the values of Jäger et al.<sup>6</sup> are lower than those of Gillotay et al.<sup>3</sup> by as much as 20%. In this region the values of Chou et al.<sup>2</sup> and Meller et al.<sup>7</sup> are between those of Gillotay et al.<sup>3</sup> and Jäger et al.<sup>6</sup>

The recommended absorption cross sections in Table 4F-31 are averages over 500 cm<sup>-1</sup> intervals of the values of Gillotay et al.<sup>3</sup> in the region 168.10–173.15 nm, the mean of the values from Gillotay et al.<sup>3</sup> and Jäger et al.<sup>6</sup> in the region 174.65–182.65 nm, the mean of the values from Chou et al.,<sup>2</sup> Gillotay et al.,<sup>3</sup> and Jäger et al.<sup>6</sup> in the region 184.35–199.00 nm, the mean of the values of Chou et al.,<sup>2</sup> Gillotay et al.,<sup>3</sup> Meller et al.,<sup>7</sup> and Jäger et al.<sup>6</sup> in the region 201.01–218.59 nm, the mean of the values from Chou et al.,<sup>2</sup> Gillotay et al.,<sup>3</sup> and Meller et al.<sup>7</sup> in the region 221.00–226.00 nm, and the mean of the values from Gillotay et al.<sup>3</sup> and Meller et al.<sup>7</sup> in the region 228.58–305.36 nm.

The temperature dependence of the absorption spectrum has been measured by Gillotay et al.<sup>3</sup> (166–308 nm) over the range 210–295 K. The temperature dependence is significant only in the region <175 nm and >250 nm. The strong absorption band is shifted slightly to shorter wavelengths with decreasing temperature and a peak cross section increase of ~20% between 295 and 210 K. In the long wavelength region, the absorption cross sections decrease with decreasing temperature with a decrease of ~80% at 305 nm between 295 and 210 K.

*Photolysis Quantum Yield and Product Studies:* Phosgene is a useful actinometer in the region 200–280 nm. The photodissociation processes  $\text{COCl}_2 + \text{hv} \rightarrow \text{COCl} + \text{Cl}$  with subsequent decay of the  $\text{COCl}$  radical,  $\text{COCl} \rightarrow \text{CO} + \text{Cl}$ , produces CO with unity quantum yield (see Okabe,<sup>8</sup> Wijnen,<sup>11</sup> Heicklen,<sup>5</sup> and Calvert and Pitts<sup>1</sup>).

**F31. COHCl (formyl chloride)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of formyl chloride, COHCl, has been measured at room temperature by Libuda et al.<sup>1</sup> (239–307 nm). The absorption spectrum has a highly structured absorption band with a maximum near 260 nm. The recommended cross sections in Table 4F-32 are the averages over 1 nm intervals of the data from Libuda et al.<sup>1</sup> (0.7 nm resolution).

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4F-32. Recommended Absorption Cross Sections of COHCl at 298 K**

λ (nm)	10 <sup>20</sup> σ (cm <sup>2</sup> )

(2)

(3)

(Recommendation: 94-26, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of COFCl (carbonyl chlorofluoride, fluorochlorophosgene) has been measured at room temperature by Chou et al.<sup>1</sup> (186–226 nm), Hermann et al.<sup>2</sup> (193.4 nm), and Nölle et al.<sup>3,4</sup> (200–262 nm). The spectrum has monotonically decreasing absorptions cross sections with increasing wavelength with a shoulder in the spectrum around 200 nm. The room temperature data are in good agreement in the common wavelength range with differences ≤6%. The recommended absorption cross sections in Table 4F-33 are the averages over the 500 cm<sup>-1</sup> intervals used for atmospheric modeling of the data from Chou et al.<sup>1</sup> and Hermann et al.<sup>2</sup> in the region 186–199 nm, the mean of the data from Chou et al.,<sup>1</sup> and Nölle et al.<sup>3,4</sup> at 201 and 203.1 nm, and the data from Nölle et al.<sup>3,4</sup> at wavelengths >205 nm.

The temperature dependence of the absorption spectrum was measured by Nölle et al.<sup>3,4</sup> (200–262 nm) at 223, 248, 273, and 298 K. The cross sections decrease with decreasing temperature at wavelengths >210 nm with the magnitude of the difference increasing with increasing wavelength. At wavelengths <210 nm the cross

sections increase with decreasing temperature with the difference in going from 298 to 223 K is ~18% at 201 nm.

**Photolysis Quantum Yield and Product Studies:** Photolysis quantum yields of COFCl have been measured by Hermann et al.<sup>2</sup> and Nölle et al.<sup>4</sup> The results are summarized in Table 4F-34. The relative distribution of the CO and COF<sub>2</sub> products was shown by Hermann et al.<sup>2</sup> to depend on the total pressure over the range 10 to 900 mbar. The apparent quantum yields were taken as the quantum yields for the decomposition into COF + Cl and CO + F + Cl since the parent molecule cannot be reformed (as in the case of COF<sub>2</sub>) and COCl is known to be unstable.

**Table 4F-33. Recommended Absorption Cross Sections of COFCl at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

### F33. CFCl<sub>3</sub> (fluorotrichloromethane, CFC-11)

[Back to Index](#)

(1)

(Recommendation: 15–10, Note: 15–10, Evaluated: 15–10)

**Absorption Cross Sections:** The VUV/UV absorption spectrum of fluorotrichloromethane (CFC-11), CFCl<sub>3</sub>, has been measured at room temperature by Gilbert et al.<sup>4</sup> (60–145 nm), Doucet et al.<sup>3</sup> (120–200 nm), Gordus and Bernstein<sup>5</sup> (225 nm), Rowland and Molina<sup>14</sup> (186–226 nm), Robbins and Stolarski<sup>13</sup> (174–226 nm), Greene and Wayne<sup>6</sup> (186–209 nm), Chou et al.<sup>1</sup> (185–226 nm), Hubrich et al.<sup>8</sup> (158–260 nm), Hubrich and Stuhl<sup>7</sup> (158–260 nm), Vanlaethem-Meurée et al.<sup>16</sup> (190–220 nm), Simon et al.<sup>15</sup> (174–230 nm), Mérianne et al.<sup>12</sup> (200–238 nm), and McGillen et al.<sup>11</sup> (184.95–230 nm). Absorption cross sections in the region 148–225

nm have also been derived from electron energy loss measurements by Huebner et al.<sup>9</sup>, which are up to 30% higher than the values obtained by optical measurements. The room temperature data for wavelengths >180 nm are in good agreement, generally within 10–15%. The recommended absorption cross sections in Table 4F-35 are the values from Simon et al.<sup>15</sup> in the region 174–188 nm, the values from the McGillen et al. parameterization (see below) in the region 190–230 nm, and the data from Hubrich and Stuhl<sup>7</sup> in the region 235–260 nm. An uncertainty factor of 1.04 (2 $\sigma$ ) is recommended for the 190–230 nm wavelength region.

A recommended Lyman- $\alpha$  cross section of  $9.8 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  with an uncertainty factor of 1.20 (2 $\sigma$ ) is taken from SPARC.<sup>10</sup>

The temperature dependence of the absorption spectrum was measured by Chou et al.<sup>1</sup> (185–226 nm) over the range 213–296 K, Hubrich et al.<sup>8</sup> (158–260 nm) and Hubrich and Stuhl<sup>7</sup> (158–260 nm) at 208 and 298 K, Vanlaethem-Meurée et al.<sup>16</sup> (190–220 nm) at 255, 279, and 296 K, Simon et al.<sup>15</sup> (174–230 nm) over the range 225–295 K, Mérienne et al.<sup>12</sup> (200–238 nm) at 220, 240, and 296 K, and McGillen et al.<sup>11</sup> (184.95–230 nm) at 5 temperatures between 216 and 296 K. The temperature dependence is significant at wavelengths above 185 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>15</sup> parameterized their cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A<sub>n</sub> and B<sub>n</sub>, valid for the temperature range 210–300 K and wavelength range 174–230 nm are:

$$\begin{array}{ll} A_0 = -84.611 & B_0 = -5.7912 \\ A_1 = 7.9551 \times 10^{-1} & B_1 = 1.1689 \times 10^{-1} \\ A_2 = -2.0550 \times 10^{-3} & B_2 = -8.8069 \times 10^{-4} \\ A_3 = -4.4812 \times 10^{-6} & B_3 = 2.9335 \times 10^{-6} \\ A_4 = 1.5838 \times 10^{-8} & B_4 = -3.6421 \times 10^{-9} \end{array}$$

Mérienne et al.<sup>12</sup> used a similar polynomial expansion to fit their data to

$$\ln \sigma(\lambda, T) = \sum a_n (\lambda-200)^n + (T-296) \times \sum b_n (\lambda-200)^n,$$

which is valid for the temperature range 220–296 K and wavelength range 200–238 nm. The reported a<sub>n</sub> and b<sub>n</sub> parameters are:

$$\begin{array}{ll} a_0 = -41.925548 & b_0 = 3.58977 \times 10^{-4} \\ a_1 = -1.142857 \times 10^{-1} & b_1 = 3.02973 \times 10^{-4} \\ a_2 = -3.12034 \times 10^{-3} & b_2 = -1.13 \times 10^{-8} \\ a_3 = 3.6699 \times 10^{-5} & \end{array}$$

McGillen et al.<sup>11</sup> used the polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_i (\lambda-200)^i + (T-273) \times \sum B_i (\lambda-200)^i$$

to fit their data. The fit is valid for the temperature range 216–296 K and wavelength range 190–230 nm and reproduces their experimental data to within 2%. The reported A<sub>i</sub> and B<sub>i</sub> parameters are given below. The fit is in good agreement with the Chou et al.<sup>1</sup> data set, to within 5%, in reasonable agreement with the Mérienne et al.<sup>12</sup> data set, differences of 8% or less, but shows systematic differences with the Simon et al. data set, with 15% differences for the data at 230 K. The McGillen et al. parameterization is recommended.

i	A <sub>i</sub>	B <sub>i</sub>
0	-18.1863	0.0002656
1	-0.0528	$4.228 \times 10^{-5}$
2	-0.001126	$1.4027 \times 10^{-6}$
3	$-3.0552 \times 10^{-5}$	$6.44645 \times 10^{-7}$
4	$2.24126 \times 10^{-6}$	$-3.8038 \times 10^{-8}$
5	$-3.2064 \times 10^{-8}$	$5.99 \times 10^{-10}$

*Photolysis Quantum Yield and Product Studies:* Clark and Husain<sup>2</sup> reported a quantum yield for Cl\*(<sup>2</sup>P<sub>1/2</sub>) atom formation in the broadband photolysis of CFCl<sub>3</sub> of  $0.79 \pm 0.27$ .

#### F34. CF<sub>2</sub>Cl<sub>2</sub> (difluorodichloromethane, CFC-12)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of difluorodichloromethane (CFC-12), CF<sub>2</sub>Cl<sub>2</sub>, has been measured at room temperature by Gordus and Bernstein<sup>5</sup> (210 nm), Rowland and Molina<sup>14</sup> (186–216 nm), Robbins and Stolarski<sup>13</sup> (174–216 nm), Greene and Wayne<sup>6</sup> (186–206 nm), Rebbert and Ausloos<sup>12</sup> (213.9 nm), Chou et al.<sup>1</sup> (184–221 nm), Hubrich et al.<sup>7</sup> (159–240 nm), Vanlaethem-Meurée et al.<sup>17</sup> (190–216 nm), Simon et al.<sup>16</sup> (174–230 nm), and Mérienne et al.<sup>11</sup> (200–231 nm). The room temperature data are in good agreement, generally within 10–15%, except for data from Green and Wayne<sup>6</sup> at wavelengths >195 nm and the data from Rowland and Molina<sup>14</sup> near 210 nm. Absorption cross sections have also been derived from electron energy loss measurements by Huebner et al.<sup>8</sup> (148–218 nm), which agree to within 10% with the data obtained by optical measurements around the absorption maximum but are larger than the optical cross section data at wavelengths >196 nm by as much as 100%. The recommended absorption cross sections in Table 4F-36 are values from Hubrich et al.<sup>7</sup> in the region 170–172 nm, the mean of the values reported by Hubrich et al.<sup>7</sup> and Simon et al.<sup>16</sup> in the region 174–178 nm, the values from Simon et al.<sup>16</sup> in the region 180–198 nm, mean of the values reported by Simon et al.<sup>16</sup> and Mérienne et al.<sup>11</sup> in the region 200–226 nm, and the data of Mérienne et al.<sup>11</sup> in the region 228–230 nm. For the range 232–240 nm the recommended values were obtained from a log-linear fit and extrapolation of the Mérienne et al.<sup>11</sup> data,  $\log \sigma(\lambda) = 2.1448 - 0.1061 \lambda$ . The measured cross section values from Hubrich et al.<sup>7</sup> over this wavelength range are lower by ~40% at 240 nm than the extrapolated values. An uncertainty factor of 1.08 (2 $\sigma$ ) is recommended for the 190–230 nm wavelength region.<sup>9</sup>

High resolution absorption cross section measurements have been carried out by Seccombe et al.<sup>15</sup> (50–150 nm) and Limao-Vieira et al.<sup>10</sup> (113–225 nm) using a synchrotron radiation light source. The results of Limao-Vieira et al.<sup>10</sup> for the absorption band at 170–204 nm are in very good agreement with the recommendation in Table 4F-36. These cross section measurements significantly improve upon the earlier data from Gilbert et al.<sup>4</sup> (60–135 nm) and Doucet et al.<sup>3</sup> (120–200 nm).

The temperature dependence of the absorption spectrum has been measured by Rebbert and Ausloos<sup>12</sup> (213.9 nm) over the range 234–442 K, Chou et al.<sup>1</sup> (184–221 nm) at 212, 252, and 296 K, Hubrich et al.<sup>7</sup> (159–240 nm) at 208 and 298 K, Vanlaethem-Meurée et al.<sup>17</sup> (190–216 nm) at 255, 279, and 296 K, Simon et al.<sup>16</sup> (174–230 nm) at 225–295 K, and Mérienne et al.<sup>11</sup> (200–231 nm) at 220, 240, and 296 K.

The temperature dependence is significant at wavelengths above 186 nm where the cross sections decrease with decreasing temperature. Mérienne et al.<sup>11</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\ln \sigma(\lambda, T) = \sum a_n (\lambda - 200)^n + (T - 296) \times \sum b_n (\lambda - 200)^n$$

that is valid for the temperature range 220–296 K and wavelength range 200–231 nm. The a<sub>n</sub> and b<sub>n</sub> parameters given below are recommended.

$$\begin{aligned} a_0 &= -43.8954569 & b_0 &= 4.8438 \times 10^{-3} \\ a_1 &= -2.403597 \times 10^{-1} & b_1 &= 4.96145 \times 10^{-4} \\ a_2 &= -4.2619 \times 10^{-4} & b_2 &= -5.6953 \times 10^{-6} \\ a_3 &= 9.8743 \times 10^{-6} \end{aligned}$$

Simon et al.<sup>16</sup> also parameterized the cross section temperature dependence of their data. However, the parameters reported by Simon et al.<sup>16</sup> contain typographical error(s) that were reproduced in JPL02-25. The correct parameters are unknown and therefore not given here.

*Photolysis Quantum Yield and Product Studies:* Clark and Husain<sup>2</sup> report the quantum yield for Cl\*(<sup>2</sup>P<sub>1/2</sub>) atom formation in the broad band photolysis of CF<sub>2</sub>Cl<sub>2</sub> to be 0.75 ± 0.26.

### F35. CF<sub>3</sub>Cl (trifluorochloromethane, CFC-13)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of trifluorochloromethane (CFC-13), CF<sub>3</sub>Cl, has been measured at room temperature by Chou et al.<sup>1</sup> (184–203 nm), Vanlaethem-Meurée et al.<sup>8</sup> (172–200 nm), Hubrich and Stuhl<sup>5</sup> (160–220 nm), and Simon et al.<sup>7</sup> (172–200 nm). The cross section values from Vanlaethem-Meurée et al.<sup>8</sup> and Simon et al.<sup>7</sup> are identical. The cross section data from Hubrich and Stuhl<sup>5</sup> deviate from the Vanlaethem-Meurée et al.<sup>8</sup> and Simon et al.<sup>7</sup> values by ±25% and the data from Chou et al.<sup>1</sup> is systematically greater by 15–30% in the region 185–200 nm. The recommended absorption cross sections in Table 4F-37 are taken from Simon et al.<sup>7</sup> for the range 172–200 nm. The recommended cross sections in the range 202–220 nm were obtained by a log-linear extrapolation of the Simon et al.<sup>7</sup> data,  $\log \sigma(\lambda) = -5.048 - 0.0834 \lambda$ .

The absorption spectrum has been measured in the far UV by Gilbert et al.<sup>4</sup> (65–130 nm), and Doucet et al.<sup>3</sup> (120–160 nm), and Ravishankara et al.<sup>6</sup> (Lyman- $\alpha$ , 121.6 nm).

The temperature dependence of the absorption spectrum was measured by Vanlaethem-Meurée et al.<sup>8</sup> (172–200 nm) at 255, 279, and 296 K, Hubrich and Stuhl<sup>5</sup> (160–220 nm) at 208 and 298 K, and Simon et al.<sup>7</sup> (172–200 nm) over the range 225–295 K. Vanlaethem-Meurée et al.<sup>8</sup> and Simon et al.<sup>7</sup> reported no measurable temperature dependence. Hubrich and Stuhl<sup>5</sup> report a decrease of the absorption cross sections at 208 K, 4% at 160 nm increasing to 74% at 205 nm. Simon et al.<sup>7</sup> parameterized the cross section wavelength dependence and the temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n \quad (\text{with all } B_n = 0)$$

and reported calculated values at 295 K. The A<sub>n</sub> parameters, which are valid for the temperature range 210–300 K and wavelength range 172–200 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -155.88 & A_1 = 2.0993 \\ A_2 = -1.0486 \times 10^{-2} & A_3 = 1.6718 \times 10^{-5} \end{array}$$

*Photolysis Quantum Yield and Product Studies:* Clark and Husain<sup>2</sup> report a quantum yield for Cl\*(<sup>2</sup>P<sub>1/2</sub>) atom formation in the broad band photolysis of CF<sub>3</sub>Cl to be 0.86 ± 0.29.

**F36. CF<sub>2</sub>ClCFCl<sub>2</sub> (1,1,2-trifluoro-1,2,2-trichloroethane, CFC-113)**

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of 1,1,2-trifluoro-1,2,2-trichloroethane (CFC-113), CF<sub>2</sub>ClCFCl<sub>2</sub>, has been measured at room temperature by Chou et al.<sup>1</sup> (184–224 nm), Hubrich and Stuhl<sup>3</sup> (160–250 nm), and Simon et al.<sup>4</sup> (184–230 nm). The cross section values agree to within ~10% except in the region near 190 nm where the values of Hubrich and Stuhl<sup>3</sup> are smaller by as much as 20%. The recommended absorption cross sections in Table 4F-38 are the values from Hubrich and Stuhl<sup>3</sup> in the region 175–180 nm, the value at 184 nm was interpolated between those of Hubrich and Stuhl<sup>3</sup> at 180 nm and Simon et al.<sup>4</sup> at 186 nm, and the values from Simon et al.<sup>4</sup> in the region 186–230 nm. The recommended absorption cross sections for wavelengths >230 nm were obtained from a log-linear extrapolation of the Simon et al.<sup>4</sup> data, log σ(λ)= -0.9860–0.0894 λ. The values measured by Hubrich and Stuhl<sup>3</sup> in the region >230 nm are greater than the extrapolated values by ~20–80% .

The absorption spectrum in the far UV has been measured by Doucet et al.<sup>2</sup> (110–200 nm).

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl<sup>3</sup> (160–250 nm) at 208 and 298 K and Simon et al.<sup>4</sup> (184–230 nm) over the range 225–295 K. The temperature dependence is significant at wavelengths >194 nm and <170 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>4</sup> parameterized the temperature dependence of the cross sections using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, valid over the temperature range 210–300 K and wavelength range 182–230 nm, given below are recommended.

A <sub>0</sub> = -1087.9	B <sub>0</sub> = 12.493
A <sub>1</sub> = 20.004	B <sub>1</sub> = -2.3937 × 10 <sup>-1</sup>
A <sub>2</sub> = -1.3920 × 10 <sup>-1</sup>	B <sub>2</sub> = 1.7142 × 10 <sup>-3</sup>
A <sub>3</sub> = 4.2828 × 10 <sup>-4</sup>	B <sub>3</sub> = -5.4393 × 10 <sup>-6</sup>
A <sub>4</sub> = -4.9384 × 10 <sup>-7</sup>	B <sub>4</sub> = 6.4548 × 10 <sup>-9</sup> .

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F37. CF<sub>2</sub>ClCF<sub>2</sub>Cl (1,1,2,2-tetrafluoro-1,2-dichloroethane, CFC-114)**[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of 1,1,2,2-tetrafluoro-1,2-dichloroethane (CFC-114), CF<sub>2</sub>ClCF<sub>2</sub>Cl, has been measured at room temperature by Chou et al.<sup>1</sup> (184–219 nm), Hubrich and Stuhl<sup>3</sup> (160–235 nm), and Simon et al.<sup>5</sup> (172–220 nm). The room temperature values of Simon et al.<sup>5</sup> and Chou et al.<sup>1</sup> agree to within 5% except at 185 and 195 nm. The cross section values from Hubrich and Stuhl<sup>3</sup> are systematically greater than those from Simon et al.<sup>5</sup> The recommended absorption cross sections in Table 4F-39 are the values from Simon et al.<sup>5</sup> in the region 172–220 nm. The recommended cross sections for wavelengths >220 nm were obtained from a log-linear extrapolation of the Simon et al.<sup>5</sup> data,  $\log \sigma(\lambda) = -1.8233 - 0.0913 \lambda$ . The values measured by Hubrich et al.<sup>3</sup> are greater by ~40% than the extrapolated values.

The absorption spectrum in the far UV has been measured by Ravishankara et al.<sup>4</sup> (Lyman- $\alpha$ , 121.6 nm) and Doucet et al.<sup>2</sup> (110–190 nm).

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl<sup>3</sup> (160–235 nm) at 208 and 298 K and Simon et al.<sup>5</sup> (182–220 nm) in the range 225–295 K. Simon et al.<sup>5</sup> report decreasing cross sections with decreasing temperature for wavelengths >190 nm. Hubrich and Stuhl<sup>3</sup> report a small decrease of the cross sections (generally <10%) for wavelengths in the range 160–210 nm. Simon et al.<sup>5</sup> parameterized the temperature dependence of the cross sections using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, valid for the temperature range 210–300 K and wavelength range 172–220 nm, given below are recommended.

$$\begin{array}{ll}

### F38. CF<sub>3</sub>CF<sub>2</sub>Cl (pentafluorochloroethane, CFC-115)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of pentafluorochloroethane (CFC-115), CF<sub>3</sub>CF<sub>2</sub>Cl, has been measured at room temperature by Chou et al.<sup>1</sup> (184–207 nm), Hubrich and Stuhl<sup>3</sup> (160–230 nm), and Simon et al.<sup>5</sup> (172–204 nm). The room temperature cross section data of Simon et al.<sup>5</sup> and Hubrich and Stuhl<sup>3</sup> agree to within ~20% with the Hubrich and Stuhl<sup>3</sup> values being systematically greater over the range 172–204 nm. The data of Chou et al.<sup>1</sup> are greater than those of Simon et al.<sup>5</sup> by as much as 50%. The recommended absorption cross sections in Table 4F-40 are the mean of the values reported by Hubrich and Stuhl<sup>3</sup> and Simon et al.<sup>5</sup> in the region 172–204 nm. The recommended values for wavelengths >204 nm are the mean of the values measured by Hubrich and Stuhl<sup>3</sup> and those obtained by extrapolating the Simon et al.<sup>5</sup> data,  $\log \sigma(\lambda) = -6.2191 - 0.0756 \lambda$ , where the extrapolated values are greater than the values measured by Hubrich and Stuhl.<sup>3</sup>

The absorption spectrum has been measured in the far UV by Ravishankara et al.<sup>4</sup> (Lyman- $\alpha$ , 121.6 nm) and Doucet et al.<sup>2</sup> (120–175 nm).

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl<sup>3</sup> (160–230 nm) at 208 and 298 K and Simon et al.<sup>5</sup> (172–204 nm) over the range 225–295 K. No measurable temperature dependence was reported in these studies. Simon et al.<sup>5</sup> parameterized the absorption cross sections using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n \text{ (with all } B_n = 0)$$

and reported calculated values for  $T = 295$  K. The  $A_n$  parameters, which are valid for the temperature range 210–300 K and wavelength range 172–204 nm, given below are recommended.

$$\begin{array}{ll} A_0 = 5.8281 & A_1 = -2.990 \times 10^{-1} \\ A_2 = 1.3525 \times 10^{-3} & A_3 = -2.6851 \times 10^{-6} \end{array}$$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

### F39. $\text{CHFCl}_2$ (fluorodichloromethane, HCFC-21)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of fluorodichloromethane (HCFC-21),  $\text{CHFCl}_2$ , has been measured at room temperature by Gordus and Bernstein<sup>3</sup> (208 nm), Robbins and Stolarski<sup>7</sup> (174–222 nm), Green and Wayne<sup>4</sup> (184–205 nm), Rebbert et al.<sup>6</sup> (213.9 nm), Hubrich et al.<sup>5</sup> (158–235 nm), and Simon et al.<sup>8</sup> (174–222 nm). The absorption cross section data from these groups are in good agreement, generally to within 15%, except those from Green and Wayne<sup>4</sup> which deviate significantly. The data from Hubrich et al.<sup>5</sup> also contain irregular values around 205 and 220 nm where the agreement is only ~40%. The recommended absorption cross sections in Table 4F-41 are the values of Simon et al.<sup>8</sup> in the region 174–222 nm. The recommended values for wavelengths >222 nm were obtained from a log-linear extrapolation of the Simon et al.<sup>8</sup> data,  $\log \sigma(\lambda) = 0.9806 - 0.1013 \lambda$ . The values measured by Hubrich et al.<sup>5</sup> deviate from the extrapolated values significantly.

Measurements in the far UV at 60–120 nm have been reported by Gilbert et al.,<sup>2</sup> measurements at 120–200 nm by Doucet et al.,<sup>1</sup> and a measurement at 147 nm by Rebbert et al.<sup>6</sup>

The temperature dependence of the absorption spectrum has been measured by Hubrich et al.<sup>5</sup> (158–235 nm) at 208 and 298 K and Simon et al.<sup>8</sup> (174–222 nm) over the range 225–295 K. The temperature dependence is significant at wavelengths >190 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>8</sup> parameterized the temperature dependence of the cross sections using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated values for  $T = 210, 230, 250, 270$ , and  $295\text{ K}$ . The  $A_n$  and  $B_n$  parameters, valid for the temperature range  $210\text{--}300\text{ K}$  and wavelength range  $174\text{--}222\text{ nm}$ , given below are recommended.

$A_0 = -514.56$	$B_0 = -3.0577$
$A_1 = 8.7940$	$B_1 = 6.6539 \times 10^{-2}$
$A_2 = -5.6840 \times 10^{-2}$	$B_2 = -5.3964 \times 10^{-4}$
$A_3 = 1.5894 \times 10^{-4}$	$B_3 = 1.9322 \times 10^{-6}$
$A_4 = -1.6345 \times 10^{-7}$	$B_4 = -2.5754 \times 10^{-9}$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### F40. $\text{CHF}_2\text{Cl}$ (difluorochloromethane, HCFC-22)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of difluorochloromethane (HCFC-22),  $\text{CHF}_2\text{Cl}$ , has been measured at room temperature by Robbins and Stolarski<sup>5</sup> (174–202 nm), Green and Wayne<sup>3</sup> (181–194 nm), Hubrich et al.<sup>4</sup> (158–220 nm), and Simon et al.<sup>6</sup> (174–204 nm). The results of Robbins and Stolarski,<sup>5</sup> Hubrich et al.,<sup>4</sup> and Simon et al.<sup>6</sup> are in agreement, generally to within 15–20%. However, the data from Green and Wayne<sup>3</sup> deviate significantly. The recommended absorption cross sections in Table 4F-42 are the values from Hubrich et al.<sup>4</sup> in the region 170–172 nm and the values from Simon et al.<sup>6</sup> in the region 174–204 nm. The recommended absorption cross sections for wavelengths >204 nm were obtained from a log-linear

extrapolation of the Simon et al.<sup>6</sup> data,  $\log \sigma(\lambda) = -4.1001 - 0.0870 \lambda$ . The measured values of Hubrich et al.<sup>4</sup> deviate from the extrapolated values by as much as 20%.

The absorption spectrum has been measured in the far UV by Gilbert et al.<sup>2</sup> (60–160 nm) and Doucet et al.<sup>1</sup> (120–200 nm).

The temperature dependence of the absorption spectrum has been measured by Hubrich et al.<sup>4</sup> (158–220 nm) at 208 and 298 K and Simon et al.<sup>6</sup> (174–204 nm) over the range 225–295 K. A weak temperature dependence was observed for wavelengths >190 nm where the cross sections decrease with decreasing temperature. Simon et al.<sup>6</sup> parameterized the cross sections temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, valid for the temperature range 210–300 K and wavelength range 174–204 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -106.029 & B_0 = -1.3399 \times 10^{-1} \\ A_1 = 1.5038 & B_1 = 2.7405 \times 10^{-3} \\ A_2 = -8.2476 \times 10^{-3} & B_2 = -1.8028 \times 10^{-5} \\ A_3 = 1.4206 \times 10^{-5} & B_3 = 3.8504 \times 10^{-8} \end{array}$$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F41. CH<sub>2</sub>FCI (fluorochloromethane, HCFC-31)**[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of fluorochloromethane (HCFC-31), CH<sub>2</sub>FCI, has been measured at 208 and 298 K over the wavelength range 160–230 nm by Hubrich and Stuhl.<sup>3</sup> The recommended room temperature cross sections from this study are listed in Table 4F-43.

The absorption spectrum has been measured in the far UV by Gilbert et al.<sup>2</sup> (60–120 nm) and Doucet et al.<sup>1</sup> (120–200 nm). The cross section values reported by Doucet et al. are significantly greater than those of Hubrich and Stuhl<sup>3</sup> for the common wavelength region.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F42. CF<sub>3</sub>CHCl<sub>2</sub> (1,1,1-trifluoro-2,2-dichloroethane, HCFC-123)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of 1,1,1-trifluoro-2,2-dichloroethane (HCFC-123), CF<sub>3</sub>CHCl<sub>2</sub>, has been measured at room temperature by Green and Wayne<sup>2</sup> (185–204 nm), Gillotay and Simon<sup>1</sup> (170–250 nm), Orlando et al.<sup>4</sup> (190–230 nm), and Nayak et al.<sup>3</sup> (160–230 nm). The absorption cross sections are within 25% of each other in the region below 220 nm with the exception of the Green and Wayne<sup>2</sup> data that are significantly lower at wavelengths <200 nm. The recommended absorption cross sections in Table 4F-44 are the mean of the values reported by Gillotay and Simon<sup>1</sup> and Nayak et al.<sup>3</sup> in the region 170–188 nm and the mean of the values reported by Gillotay and Simon,<sup>1</sup> Orlando et al.,<sup>4</sup> and Nayak et al.<sup>3</sup> in the region 190–230 nm. The recommended cross sections for wavelengths >230 nm were obtained using a log-linear extrapolation of the Orlando et al.<sup>4</sup> data,  $\log \sigma(\lambda) = -3.1097 - 0.0794 \lambda$ .

The temperature dependence of the absorption spectrum has been reported by Gillotay and Simon<sup>1</sup> (170–250 nm) at 225–295 K, Orlando et al.<sup>4</sup> (190–230 nm) over the range 203–295 K, and Nayak et al.<sup>3</sup> (160–230 nm)

over the range 223–333 K. These studies report a decrease of the absorption cross sections with decreasing temperature at wavelengths >180 nm and <170 nm. Between 170–180 nm, an increase in the cross section with decreasing temperature was reported by Gillotay and Simon<sup>1</sup> and Nayak et al.<sup>3</sup> An irregular temperature dependence was reported by Orlando et al.<sup>4</sup> for the range 210–230 nm where the absorption spectra show wiggles.

Various empirical functional forms have been proposed to parameterize the temperature dependence of the absorption cross sections. Gillotay and Simon<sup>1</sup> parameterized the cross sections and the temperature dependence using the polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, valid for the temperature range 210–300 K and wavelength range 182–250 nm, are given below.

$$\begin{array}{ll} A_0 = -513.996354 & B_0 = 1.757133 \\ A_1 = 9.089141 & B_1 = -3.499205 \times 10^{-2} \\ A_2 = -6.136794 \times 10^{-2} & B_2 = 2.593563 \times 10^{-4} \\ A_3 = 1.814826 \times 10^{-4} & B_3 = -8.489357 \times 10^{-7} \\ A_4 = -1.999514 \times 10^{-7} & B_4 = 1.037756 \times 10^{-9} \end{array}$$

Nayak et al.<sup>3</sup> used a sixth-order polynomial of the form

$$\log_{10} (\sigma_T) = \sum C_n (\lambda - 170)^n$$

for the temperatures measured in their study for the wavelength range 160–230 nm. The C<sub>n</sub> parameters are listed below.

	223 K	273 K	295 K	333 K
C <sub>0</sub>	-17.6732	-17.6773	-17.6792	-17.6722
C <sub>1</sub>	$1.70233 \times 10^{-2}$	$1.3636 \times 10^{-2}$	$1.19392 \times 10^{-2}$	$9.07941 \times 10^{-3}$
C <sub>2</sub>	$-7.39366 \times 10^{-4}$	$-4.98553 \times 10^{-4}$	$-3.71661 \times 10^{-4}$	$-1.29566 \times 10^{-4}$
C <sub>3</sub>	$-1.83761 \times 10^{-4}$	$-1.70566 \times 10^{-4}$	$-1.61218 \times 10^{-4}$	$-1.56667 \times 10^{-4}$
C <sub>4</sub>	$7.80778 \times 10^{-6}$	$6.73373 \times 10^{-6}$	$6.03101 \times 10^{-6}$	$5.56409 \times 10^{-6}$
C <sub>5</sub>	$-1.29836 \times 10^{-7}$	$-1.02726 \times 10^{-7}$	$-8.76762 \times 10^{-8}$	$-7.77379 \times 10^{-8}$
C <sub>6</sub>	$8.05415 \times 10^{-10}$	$5.66688 \times 10^{-10}$	$4.61745 \times 10^{-10}$	$3.93859 \times 10^{-10}$

Orlando et al.<sup>4</sup> used the expression

$$\ln \sigma(\lambda, T) = \sum (\sum a_{ij} (T - 245.4)^{j-1}) (\lambda - 206.214)^{i-1}, \quad i = 1-4, j = 1-3$$

that is valid for the temperature range 203–295 K and wavelength range 190–230 nm. The coefficients are given below.

$$\begin{array}{lll} a_{11} = -4.500 \times 10^1 & a_{12} = 3.529 \times 10^{-3} & a_{13} = -4.181 \times 10^{-8} \\ a_{21} = -1.985 \times 10^{-1} & a_{22} = 6.826 \times 10^{-5} & a_{23} = 1.555 \times 10^{-6} \\ a_{31} = -2.802 \times 10^{-4} & a_{32} = -1.018 \times 10^{-5} & a_{33} = 4.037 \times 10^{-8} \\ a_{41} = 6.312 \times 10^{-5} & a_{42} = -3.055 \times 10^{-7} & a_{43} = -2.473 \times 10^{-9} \end{array}$$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### F43. $\text{CF}_3\text{CHFCI}$ (1,1,1,2-tetrafluoro-2-chloroethane, HCFC-124)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of 1,1,1,2-tetrafluoro-2-chloroethane (HCFC-124),  $\text{CF}_3\text{CHFCI}$ , has been measured by Orlando et al.<sup>2</sup> (190–230 nm) over the range 203–295 K and Gillotay and Simon<sup>1</sup> (170–230 nm) over the range 210–295 K. The absorption cross sections from these studies agree to better than 10% between 190 and 220 nm. At wavelengths >220 nm the values of Orlando et al.<sup>2</sup> are greater than those of Gillotay and Simon<sup>1</sup> by as much as 133%. The recommended room temperature cross sections in Table 4F-45 are the values of Gillotay and Simon<sup>1</sup> in the region 170–188 nm and 222–230 nm and the mean of the values reported by Gillotay and Simon<sup>1</sup> and Orlando et al.<sup>2</sup> in the region 190–220 nm.

The absorption cross sections decrease with decreasing temperature. An irregular temperature behavior was reported by Orlando et al.<sup>2</sup> for the range 215–230 nm where the absorption spectra show wiggles. Gillotay and Simon<sup>1</sup> parameterized the cross sections and the temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for  $T = 210, 230, 250, 270$ , and  $295\text{ K}$ . The  $A_n$  and  $B_n$  parameters, valid for the temperature range 210–300 K and wavelength range 170–230 nm, are given below.

$$\begin{array}{ll} A_0 = -101.230250 & B_0 = -5.795712 \times 10^{-2} \\ A_1 = 1.333519 & B_1 = 1.053901 \times 10^{-3} \\ A_2 = -6.888672 \times 10^{-3} & B_2 = -6.530379 \times 10^{-6} \\ A_3 = 1.114172 \times 10^{-5} & B_3 = 1.382056 \times 10^{-8} \end{array}$$

Orlando et al.<sup>2</sup> report a parameterization using the expression

$$\ln \sigma(\lambda, T) = \sum (\sum a_{ij} (T-251.7)^{j-1}) (\lambda-206.214)^{i-1}, \quad i = 1-4, j = 1-3$$

for the temperature range 203–295 K and wavelength range 190–230 nm. The reported coefficients are given below.

$$\begin{array}{lll} a_{11} = -4.967 \times 10^1 & a_{12} = 6.562 \times 10^{-3} & a_{13} = 1.735 \times 10^{-5} \\ a_{21} = -2.025 \times 10^{-1} & a_{22} = 2.788 \times 10^{-4} & a_{23} = -3.974 \times 10^{-6} \\ a_{31} = 6.839 \times 10^{-4} & a_{32} = 5.523 \times 10^{-6} & a_{33} = -3.092 \times 10^{-7} \\ a_{41} = 1.275 \times 10^{-4} & a_{42} = -2.959 \times 10^{-7} & a_{43} = -1.182 \times 10^{-8} \end{array}$$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F44. CF<sub>3</sub>CH<sub>2</sub>Cl (1,1,1-trifluoro-2-chloroethane, HCFC-133a)**[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of 1,1,1-trifluoro-2-chloroethane (HCFC-133a), CF<sub>3</sub>CH<sub>2</sub>Cl, has been measured at room temperature by Ichimura et al.<sup>3</sup> (147 nm,  $\sigma = 1.35 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup>), and Green and Wayne<sup>1</sup> (186–203 nm), and at 208 and 298 K by Hubrich and Stuhl<sup>2</sup> (160–245 nm). The agreement in the absorption cross sections for wavelengths >180 nm is poor. The recommended absorption cross sections in Table 4F-46 are taken from Hubrich and Stuhl.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

F45.  $\text{CH}_3\text{CFCl}_2$  (1,1,1-fluorodichloroethane, HCFC-141b)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of 1,1,1-fluorodichloroethane (HCFC-141b),  $\text{CH}_3\text{CFCl}_2$ , has been measured over the temperature range 210–295 K by Gillotay and Simon<sup>2</sup> (170–240 nm), over the temperature range 203–295 K by Talukdar et al.<sup>3</sup> (190–230 nm), and at room temperature by Fahr et al.<sup>1</sup> (190–240 nm). Fahr et al.<sup>1</sup> also measured the absorption spectrum in the liquid-phase and used a wavelength-shift procedure to derive cross sections for the gas-phase. The agreement between the cross section values reported by Gillotay and Simon<sup>2</sup> and Fahr et al.<sup>1</sup> for the 190–240 nm region is good (1–10% up to 236 nm). The agreement of the results from Talukdar et al.<sup>3</sup> are not as good. Their absorption cross sections are smaller at wavelengths <210 nm by as much as ~20% and are greater at wavelengths >210 nm by as much as 70%. The recommended absorption cross sections in Table 4F-47 are the values of Gillotay and Simon<sup>2</sup> in the region 170–188 nm and the mean of the values reported by Gillotay and Simon<sup>2</sup> and Fahr et al.<sup>1</sup> in the region 190–240 nm.

A decrease of the absorption cross sections with decreasing temperature for wavelengths >188 nm and <172 nm was reported by Gillotay and Simon.<sup>2</sup> An increase in the cross sections with decreasing temperature was observed between 172 and 188 nm. Gillotay and Simon<sup>2</sup> parameterized the cross sections and the temperature dependence of the absorption cross sections using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n.$$

and report calculated cross section values for  $T = 210, 230, 250, 270$ , and  $295 \text{ K}$ . The  $A_n$  and  $B_n$  parameters, valid for the temperature range 210–300 K and wavelength range 172–240 nm, given below are recommended.

$A_0 = -682.913042$	$B_0 = 4.074747$
$A_1 = 12.122290$	$B_1 = -8.053899 \times 10^{-2}$
$A_2 = -8.187699 \times 10^{-2}$	$B_2 = 5.946552 \times 10^{-4}$
$A_3 = 2.437244 \times 10^{-4}$	$B_3 = -1.945048 \times 10^{-6}$
$A_4 = -2.719103 \times 10^{-7}$	$B_4 = 2.380143 \times 10^{-9}$

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### F46. CH<sub>3</sub>CF<sub>2</sub>Cl (1,1,1-difluorochloroethane, HCFC-142b)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of 1,1,1-difluorochloroethane (HCFC-142b), CH<sub>3</sub>CF<sub>2</sub>Cl, has been measured at room temperature by Doucet et al.<sup>3</sup> (120–180 nm), Green and Wayne<sup>5</sup> (184–201 nm), Hubrich and Stuhl<sup>6</sup> (160–230 nm), Gillotay and Simon<sup>4</sup> (170–230 nm), Orlando et al.<sup>8</sup> (190–230 nm), and Nayak et al.<sup>7</sup> (160–210 nm). For wavelengths <200 nm, the cross sections reported by Hubrich and Stuhl<sup>6</sup> and Nayak et al.<sup>7</sup> agree to within 15%, while those by Gillotay and Simon<sup>4</sup> and Orlando et al.<sup>8</sup> are systematically smaller by as much as 30%. Over the wavelength range 200–215 nm, the values of Gillotay and Simon,<sup>4</sup> Orlando et al.,<sup>8</sup> and Nayak et al.<sup>7</sup> agree to within 15%. For wavelengths >215 nm, the absorption spectrum reported by Orlando et al.<sup>8</sup> has wiggles and deviations of up to 100% from the data of Gillotay and Simon.<sup>4</sup> The values reported by Hubrich and Stuhl<sup>6</sup> in the range 205–230 nm have increasingly larger deviations from the values reported by Gillotay and Simon<sup>4</sup> with increasing wavelength. The results of Green and Wayne<sup>5</sup> are significantly different from all the other data sets and are not considered in the recommendation. The recommended room temperature absorption cross sections in Table 4F-48 are the mean of the values reported by Hubrich and Stuhl,<sup>6</sup> Gillotay and Simon,<sup>4</sup> and Nayak et al.<sup>7</sup> in the region 170–185 nm, the mean of the values reported by Gillotay and Simon,<sup>4</sup> Orlando et al.,<sup>8</sup> and Nayak et al.<sup>7</sup> in the region 190–210 nm, and the values reported by Gillotay and Simon<sup>4</sup> in the region 212–230 nm.

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl<sup>6</sup> (160–230 nm) at 298 and 208 K, Gillotay and Simon<sup>4</sup> (170–230 nm) over the range 210–295 K, Orlando et al.<sup>8</sup> (190–230 nm) over the range 203–295 K, and Nayak et al.<sup>7</sup> (160–210 nm) over the range at 223–333 K. A decrease of the absorption cross sections with decreasing temperature was observed by Gillotay and Simon<sup>4</sup> and Nayak et al.<sup>7</sup> over the wavelength range 160–230 nm and by Orlando et al.<sup>8</sup> between 190 and 200 nm. An irregular temperature behavior was reported by Orlando et al.<sup>8</sup> for the range 215–230 nm where the absorption spectrum at various temperatures cross. The absorption cross sections and temperature dependence have been parameterized using several different empirical functional forms. Gillotay and Simon<sup>4</sup> used the polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, valid for the temperature range 210–300 K and wavelength range 172–230 nm, are given below.

A <sub>0</sub> = -328.092008	B <sub>0</sub> = 4.289533 × 10 <sup>-1</sup>
A <sub>1</sub> = 6.342799	B <sub>1</sub> = -9.042817 × 10 <sup>-3</sup>
A <sub>2</sub> = -4.810362 × 10 <sup>-2</sup>	B <sub>2</sub> = 7.018009 × 10 <sup>-5</sup>
A <sub>3</sub> = 1.611991 × 10 <sup>-4</sup>	B <sub>3</sub> = -2.389065 × 10 <sup>-7</sup>
A <sub>4</sub> = -2.042613 × 10 <sup>-7</sup>	B <sub>4</sub> = 3.039799 × 10 <sup>-10</sup>

Nayak et al.<sup>7</sup> used the expression

$$\log_{10} (\sigma_T) = \sum C_n (\lambda - 160)^n$$

and reported coefficients for 223, 233, 253, 273, 295, 313, and 333 K and the wavelength range 160–210 nm. The reported C<sub>n</sub> parameters are given below.

	223 K	273 K	295 K	333 K
C <sub>0</sub>	-18.2361	-18.2441	-18.2406	-18.1777
C <sub>1</sub>	-1.26669 × 10 <sup>-2</sup>	-7.37889 × 10 <sup>-3</sup>	-6.48269 × 10 <sup>-3</sup>	-2.39647 × 10 <sup>-2</sup>
C <sub>2</sub>	-2.32945 × 10 <sup>-3</sup>	-2.66537 × 10 <sup>-3</sup>	-2.80923 × 10 <sup>-3</sup>	-7.23910 × 10 <sup>-4</sup>
C <sub>3</sub>	2.81933 × 10 <sup>-5</sup>	4.19193 × 10 <sup>-5</sup>	5.01979 × 10 <sup>-5</sup>	-1.08049 × 10 <sup>-5</sup>
C <sub>4</sub>	-1.37963 × 10 <sup>-7</sup>	-2.88472 × 10 <sup>-7</sup>	-3.96860 × 10 <sup>-7</sup>	1.37618 × 10 <sup>-7</sup>

Orlando et al.<sup>8</sup> used the expression

$$\ln \sigma(\lambda, T) = \sum (\sum a_{ij} (T - 245.4)^{j-1}) (\lambda - 206.214)^{i-1}, \quad i = 1-4, j = 1-3$$

for the temperature range 203–295 K and wavelength range 190–230 nm. The coefficients are given below.

$$\begin{array}{lll}
 a_{11} = -4.973 \times 10^1 & a_{12} = 9.077 \times 10^{-3} & a_{13} = -4.651 \times 10^{-5} \\
 a_{21} = -2.175 \times 10^{-1} & a_{22} = 4.712 \times 10^{-4} & a_{23} = -1.005 \times 10^{-5} \\
 a_{31} = 4.133 \times 10^{-4} & a_{32} = -6.432 \times 10^{-5} & a_{33} = 1.141 \times 10^{-6} \\
 a_{41} = 7.145 \times 10^{-5} & a_{42} = -5.396 \times 10^{-6} & a_{43} = 1.187 \times 10^{-7}
 \end{array}$$

**Photolysis Quantum Yield and Product Studies:** Quantum yields for Cl ( ${}^2\text{P}_{3/2}$ ) and Cl\* ( ${}^2\text{P}_{1/2}$ ) atom formation in the photolysis of  $\text{CH}_3\text{CF}_2\text{Cl}$  at 193.3 nm have been measured by Brownsword et al.<sup>2</sup> to be  $\Phi(\text{Cl} + \text{Cl}^*) = 0.90 \pm 0.17$  with  $\Phi(\text{Cl}) = 0.65 \pm 0.12$  and  $\Phi(\text{Cl}^*) = 0.25 \pm 0.05$ . Brownsword et al.<sup>1</sup> reported the quantum yields for H atom formation in the photolysis at 121.6 and 193.3 nm to be  $0.53 \pm 0.12$  and  $0.06 \pm 0.02$ , respectively.

#### F47. $\text{CH}_2\text{ClCHO}$ (chloroacetaldehyde)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of chloroacetaldehyde,  $\text{CH}_2\text{ClCHO}$ , has been measured at room temperature by Lucazeau and Sandorfy<sup>2</sup> (118–182 nm) and Libuda<sup>1</sup> (235–360 nm). The absorption band centered at ~290 nm has prominent diffuse band structure at wavelengths >280 nm. The recommended absorption cross sections in Table 4F-49 are the average absorption cross sections over 1 nm intervals of the spectrum reported by Libuda<sup>1</sup> (0.6 nm resolution).

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### F48. CHCl<sub>2</sub>CHO (dichloroacetaldehyde)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of dichloroacetaldehyde, CHCl<sub>2</sub>CHO, has been measured at room temperature by Lucazeau and Sandorfy<sup>2</sup> (118–182 nm) and Libuda<sup>1</sup> (253–360 nm), who report an absorption band with weak structure around the maximum at ~300 nm. The recommended absorption cross sections in Table 4F-50 are averages over 1 nm intervals of the spectrum reported by Libuda<sup>1</sup> (0.6 nm resolution).

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### F49. CF<sub>2</sub>ClCHO (difluorochloroacetaldehyde)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of difluorochloroacetaldehyde, CF<sub>2</sub>ClCHO, has been measured at room temperature by Libuda<sup>1</sup> (235–355 nm) and Rattigan et al.<sup>2</sup> (235–370 nm). The spectrum displays an absorption band over the wavelength range of the measurements with a maximum at 300 nm. The room temperature cross section data are in good agreement, within 3–10% around the peak, with the data from Rattigan et al.<sup>2</sup> being systematic greater than those of Libuda.<sup>1</sup> At wavelengths away from the peak the data from Rattigan et al.<sup>2</sup> are also greater, by 25% at 340 nm and 15 to 300% between 265 and 235 nm.

Rattigan et al.<sup>2</sup> also reported the temperature dependence of the absorption spectrum over the range 245–298 K. The cross sections increase near the peak and decrease in the long wavelength wing with decreasing temperature. Rattigan et al.<sup>2</sup> fit the measured temperature dependence with the empirical expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T - 298)$$

The recommended room temperature absorption cross sections in Table 4F-51 are the mean values of the data from Libuda<sup>1</sup> (using 1 nm averages of spectra recorded with 0.6 nm resolution) and Rattigan et al.<sup>2</sup> (5 nm averages of spectra recorded with 0.6 nm resolution) in the region 235–350 nm and the data from Rattigan et al.<sup>2</sup> in the region 355–370 nm. The temperature coefficients are taken from Rattigan et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## F50. CFCl<sub>2</sub>CHO (fluorodichloroacetaldehyde)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of fluorodichloroacetaldehyde, CFCl<sub>2</sub>CHO, has been measured at room temperature by Libuda<sup>1</sup> (235–360 nm) and Rattigan et al.<sup>2</sup> (235–370 nm). Over this wavelength range there is an absorption band with a maximum near 296 nm. The cross section data from Libuda<sup>1</sup> are greater by 10–30% than the data from Rattigan et al.<sup>2</sup> over the entire absorption band (except for a few points in the wings).

Rattigan et al.<sup>2</sup> also reported the temperature dependence of the absorption spectrum over the temperature range 253–298 K. The cross sections increase near the peak and decrease in the long wavelength wing with decreasing temperature. Rattigan et al.<sup>2</sup> fit the measured temperature dependence with the empirical expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298)$$

The recommended room temperature absorption cross sections in Table 4F-52 are the mean values of the data from Libuda<sup>1</sup> (using 1 nm averages of spectra recorded with 0.6 nm resolution) and Rattigan et al.<sup>2</sup> (5 nm averages of spectra recorded with 0.6 nm resolution) in the region 235–355 nm and the data from Rattigan et al.<sup>2</sup> in the region 360–370 nm. The temperature coefficients are taken from Rattigan et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## F51. $\text{CCl}_3\text{CHO}$ (trichloroacetaldehyde, chloral)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The absorption spectrum of trichloroacetaldehyde (chloral),  $\text{CCl}_3\text{CHO}$ , has been measured at room temperature by Lucazeau and Sandorfy<sup>3</sup> (118–182 and 250–357 nm), Libuda<sup>2</sup> (235–350 nm), Rattigan et al.<sup>4,5</sup> (200–360 nm), Gillotay et al.<sup>1</sup> (166–348 nm), and Talukdar et al.<sup>6</sup> (200–344 nm). Overlapping absorption bands were observed with a maximum near 290 nm and a strong band peaking below 180 nm. Except for the data of Lucazeau and Sandorfy,<sup>3</sup> the results for the 290 nm absorption band are in reasonable agreement with a 20% range in cross section values at 290 nm. Gillotay et al.<sup>1</sup> report the largest cross section values and Libuda<sup>2</sup> the smallest. The data sets from Rattigan et al.<sup>4</sup> and Talukdar et al.<sup>6</sup> agree to better than 10% around the absorption maximum. At longer wavelengths, the data sets from Rattigan et al.<sup>4</sup> and Talukdar et al.<sup>6</sup> are nearly identical. The cross sections from Gillotay et al.<sup>1</sup> are appreciably higher at the longer wavelengths and there is no explanation for this discrepancy. The temperature dependence of the absorption spectrum has been measured by Rattigan et al.<sup>4,5</sup> (243–296 K), Gillotay et al.<sup>1</sup> (210–295 K), and Talukdar et al.<sup>6</sup> (240–360 K). These studies are in agreement and found that the absorption cross sections decrease with decreasing temperature below ~260 nm and above ~290 nm. Rattigan et al.<sup>4</sup> and Talukdar et al.<sup>6</sup> parameterized the temperature dependence using the empirical expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298)$$

The recommended absorption cross sections and  $B(\lambda)$  temperature coefficients in Table 4F-53 are taken from Talukdar et al.<sup>6</sup>.

**Photolysis Quantum Yield and Product Studies:** Quantum yields for the production of H, O( $^3\text{P}$ ), and Cl atoms in the photolysis of  $\text{CCl}_3\text{CHO}$  at 193, 248, and 308 nm have been measured by Talukdar et al.<sup>6</sup> The yields of H and O atoms were found to be small or below the detection limit,  $\Phi(\text{O}({}^3\text{P})) < 0.02$  and  $< 0.01$  at 248 and 308

nm, respectively, and  $\Phi(\text{H}) = 0.04 \pm 0.005$ ,  $<0.01$ , and  $<0.002$  at 193, 248, and 308 nm, respectively. Cl atoms were found to be the primary photolysis product at 308 nm with  $\Phi(\text{Cl}) = 1.3 \pm 0.3$ .

**F52. CH<sub>3</sub>C(O)Cl (acetyl chloride)**
[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of acetyl chloride, CH<sub>3</sub>C(O)Cl, has been measured at room temperature by Libuda<sup>1</sup> (233–300 nm) and Maricq<sup>2</sup> (190–341 nm). In this wavelength range the spectrum has two overlapping continuous absorption bands, one centered near 240 nm and a stronger band peaking below 190 nm. Both studies report a peak cross section for the 240 nm band of  $\sim 1.16 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ . However, the wavelength dependence of the 240 nm band is significantly different in the two studies. Libuda<sup>1</sup> report a narrower band with a peak shifted to longer wavelength compared to that of Maricq.<sup>2</sup> At wavelengths >280 nm the cross section data reported by Maricq<sup>2</sup> is very noisy making any comparisons difficult. The recommended absorption cross sections in Table 4F-54 are 1 nm averages of data from Maricq<sup>2</sup> (0.5 nm resolution) for the region 191–292 nm and 1 nm averages of the data from Libuda<sup>1</sup> (0.6 nm resolution) for the region 293–302 nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F53. CH<sub>2</sub>ClC(O)Cl (chloroacetyl chloride)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of chloroacetyl chloride, CH<sub>2</sub>ClC(O)Cl, has been measured at room temperature and 234–342 nm by Libuda.<sup>1</sup> The spectrum has an absorption band with the maximum around 248 nm. Above 315 nm the data shows a somewhat irregular behavior and is considered unreliable. Therefore, the recommended absorption cross sections in Table 4F-55 are the 1 nm averages of the data from Libuda<sup>1</sup> (0.6 nm resolution) excluding this region.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**F54. CHCl<sub>2</sub>C(O)Cl (dichloroacetyl chloride)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of dichloroacetyl chloride, CHCl<sub>2</sub>C(O)Cl, has been measured at room temperature by Libuda<sup>1</sup> (235–338 nm) and Villenave et al.<sup>2</sup> (200–300 nm). The spectrum has an absorption band with the maximum around 258 nm. The reported cross sections are in very good agreement between 242 and 300 nm with the Villenave et al.<sup>2</sup> cross sections being systematically smaller by 1–10%. At shorter wavelengths the absorption cross sections reported by Libuda<sup>1</sup> are smaller by up to ~25% at 235 nm. Villenave et al.<sup>2</sup> observed a minimum near 232 nm and increasing cross sections between 230 and 220 nm. At the longer wavelengths the absorption spectrum reported by Libuda<sup>1</sup> is irregular at wavelengths >316 nm. The recommended absorption cross sections in Table 4F-56 are from Villenave et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4F-56. Recommended Absorption Cross Sections of CHCl<sub>2</sub>C(O)Cl at 298 K**

**F55. CCl<sub>3</sub>C(O)Cl (trichloroacetyl chloride)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of trichloroacetyl chloride, CCl<sub>3</sub>C(O)Cl, has been measured at room temperature by Libuda<sup>2</sup> (235–342 nm), Villenave et al.<sup>3</sup> (220–290 nm), and Gillotay et al.<sup>1</sup> (166–338 nm). The absorption spectrum has two overlapping bands with a peak near 256 nm and a stronger band at shorter wavelengths with a peak at ~176 nm. The spectra reported by Gillotay et al.<sup>1</sup> and Villenave et al.<sup>3</sup> are in good agreement. Although the absolute absorption cross sections are similar, the absorption spectrum reported by Libuda<sup>2</sup> has a significantly different wavelength dependence than reported in the other studies. Although the cross section data from Villenave et al.<sup>3</sup> and Gillotay et al.<sup>1</sup> are in good agreement, the recommended absorption cross sections in Table 4F-57 are from Gillotay et al.<sup>1</sup> (0.015 nm resolution) and are averages over the 500 cm<sup>-1</sup> and 5 nm intervals generally used in stratospheric photodissociation calculations.

The temperature dependence of the absorption spectrum has been measured by Gillotay et al.<sup>1</sup> over the temperature range 210–295 K. They report an increase in absorption cross section with increasing temperature at all wavelengths.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption cross sections of chloroacetone, CH<sub>3</sub>C(O)CH<sub>2</sub>Cl, have been measured over the temperature range 243–296 K between 210 and 370 nm by Burkholder et al.<sup>1</sup> using diode array spectroscopy (~0.6 nm resolution). The spectrum has two absorption bands, a strong band with the maximum at ~224 nm ( $3.35 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> at 296 K) and a weaker broader band with the maximum at ~292 nm ( $1.02 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> at 296 K). A systematic decrease in the absorption cross section with decreasing temperature was observed at wavelengths >290 nm. A temperature dependence of the absorption cross sections was also reported for the short wavelength absorption band. The reported values at 253 K are larger than those at 273 K below ~240 nm and even larger than those at 296 K below ~230 nm. The recommended absorption cross sections in Table 4F-60 are taken from Burkholder et al.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* Photodissociation quantum yields were measured by Burkholder et al.<sup>1</sup> to be  $0.5 \pm 0.08$  at 308 nm and 351 nm. At both wavelengths, the yields of CO and CO<sub>2</sub> were 0.50 and ~0.25, respectively. The yield of HCOOH and HCl were reported to be 0.25 and 0.5, respectively, at both photolysis wavelengths.

**F59. (E)-1,2-c-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub> ((E)-1,2-dichlorohexafluorocyclobutane)**[Back to Index](#)

(New Entry)

*Absorption Cross Sections:* The UV absorption cross sections of (E)-1,2-dichlorohexafluorocyclobutane, 1,2-c-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub>(E), have been measured by Papadimitriou et al.<sup>1</sup> (184.95–230 nm) at temperatures between 214 and 296 K. UV absorption spectra of (E)- and (Z)- isomeric mixtures (0.94:0.06 and 0.475:0.525) were measured experimentally and individual isomer spectra were determined using the measured sample mixing ratios. Over the 185–230 nm wavelength range the spectrum is continuous with a broad peak near 195 nm.

The absorption cross sections decrease nearly exponentially at wavelengths greater than ~200 nm. The (*E*)-isomer was observed to be a stronger absorber than the (*Z*)-isomer over this wavelength range. The 296 K absorption cross section uncertainty was estimated to be ~3% (2 $\sigma$ ) at all wavelengths included in their study.

Papadimitriou et al. measured the spectrum temperature dependence over the range 214–296 K. They observed a systematic decrease in absorption cross section with decreasing temperature at all wavelengths included in their study. The absorption spectrum was parameterized using the empirical formula

$$\log_{10}(\sigma(\lambda, T)) = \sum_i A_i(\lambda - 200)^i + (296 - T) \sum_i B_i(\lambda - 200)^i$$

and the optimized parameters are given in Table 4F-61. The parameterization reproduces the absorption spectrum to within the estimated measurement precision and is valid over the 190–220 nm wavelength range and 210–296 K temperature range.

**Table 4F-61. Recommended (*E*)-1,2-*c*-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub> Absorption Spectrum,  $\sigma(\lambda, T)$ , Parameterization**

i	A <sub>i</sub>	B <sub>i</sub>
0	-18.45	-0.000553
1	-0.0876	-8.036 × 10 <sup>-5</sup>
2	-0.003737	-4.24 × 10 <sup>-6</sup>
3	0.0001124	-6.01 × 10 <sup>-7</sup>
4	2.444 × 10 <sup>-6</sup>	6.00 × 10 <sup>-8</sup>
5	-9.33 × 10 <sup>-8</sup>	-1.279 × 10 <sup>-9</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for the production of Cl atoms and *c*-C<sub>4</sub>F<sub>6</sub> in the photolysis of 1,2-*c*-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub>(*E*) at 193 nm were measured by Papadimitriou et al.<sup>1</sup> A value of  $\Phi(\text{Cl}) = 1.9 \pm 0.27$  was determined for a 0.475:0.525 isomeric mixture (i.e., quantum yields for the individual isomers were not determined). A value of  $\Phi(\text{Cl}) = 2$  is recommended. The *c*-C<sub>4</sub>F<sub>6</sub> product yield in the photolysis of 1,2-*c*-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub>(*E*) was found to be  $0.7 \pm 0.1$ .

#### F60. (*Z*)-1,2-*c*-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub> ((*Z*)-1,2-dichlorohexafluorocyclobutane)

[Back to Index](#)

(1)

(New Entry)

*Absorption Cross Sections:* The UV absorption cross sections of (*Z*)-1,2-dichlorohexafluorocyclobutane, 1,2-*c*-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub>(*Z*), have been measured by Papadimitriou et al.<sup>1</sup> (184.95–230 nm) at temperatures between 214 and 296 K. UV absorption spectra of (*E*)- and (*Z*)-isomeric mixtures (0.94:0.06 and 0.475:0.525) were measured experimentally and individual isomer spectra were determined using the measured mixing ratios. The (*Z*)-isomer was found to be a significantly weaker absorber than the (*E*)-isomer over this wavelength range. The uncertainty in the (*Z*)-isomer 296 K absorption cross sections were estimated to be significantly greater than for the (*E*)-isomer, e.g. ~25% (2 $\sigma$ ) at 210 nm.

Papadimitriou et al. measured the spectrum temperature dependence over the range 214–296 K. They observed a systematic decrease in absorption cross section with decreasing temperature at all wavelengths included in their study. The absorption spectrum was parameterized using the empirical formula

$$\log_{10}(\sigma(\lambda, T)) = \sum_i A_i(\lambda - 200)^i + (296 - T) \sum_i B_i(\lambda - 200)^i$$

and the optimized parameters are given in Table 4F-62. The parameterization reproduces the absorption spectrum to within the estimated measurement precision and is valid over the 190–220 nm wavelength range and 210–296 K temperature range.

**Table 4F-62. Recommended (Z)-1,2-*c*-C<sub>4</sub>Cl<sub>2</sub>F<sub>6</sub> Absorption Spectrum,  $\sigma(\lambda, T)$ , Parameterization**

193 kJ mol<sup>-1</sup>

620 nm

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of Br<sub>2</sub>, molecular bromine, has been extensively studied as summarized in Table 4G-1.

**Table 4G-1. Summary of Br<sub>2</sub> Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength Range (nm)
Ribaud <sup>14</sup>	1919	289, 593, 893	356–608
Gray and Style <sup>3</sup>	1930	294	240–579
Acton et al. <sup>1</sup>	1936	293, 400, 531, 657, 767, 906	327.4–571.7
Seery and Britton <sup>16</sup>	1964	298	320–590
MacMillan <sup>11</sup>	1966	298	200–599
Passchier et al. <sup>12</sup>	1967	298, 348, 423, 298, 573, 648, 713	200–750
Wen and Noyes <sup>18</sup>	1972	303	220–290
Hemenway et al. <sup>5</sup>	1979	296	556–616.3
Roxlo and Mandl <sup>15</sup>	1980	298	170–230
Maric et al. <sup>10</sup>	1994	298	200–650
Hubinger and Nee <sup>6</sup>	1995	295	190–600
Tellinghuisen <sup>17</sup>	2008	295	190–300

The Br<sub>2</sub> spectrum exhibits an absorption band between 190 and 300 nm with a maximum near 223 nm and another stronger band between 300 and 600 nm, which is composed of three overlapping bands with maxima at ~412, 480, and 549 nm. The reported absorption cross sections are in very good agreement in the region of the UV-visible absorption band. Discrepancies are observed at wavelengths >550 nm, where the data of MacMillan<sup>11</sup> and Hemenway et al.<sup>5</sup> are as much as 60% and 100% lower, respectively, than the values measured in the other studies. Large discrepancies arise in the region of the absorption minimum between 230 and 340 nm due to a pressure dependent absorption component of Br<sub>2</sub> vapor, possibly due to a Br<sub>2</sub>–Br<sub>2</sub> dimer absorption. A detailed discussion of the available absorption data for Br<sub>2</sub> and an evaluation is given by Maric et al.<sup>10</sup> Maric et al. fit the most reliable data, those of Passchier et al.<sup>12</sup> and Wen and Noyes,<sup>18</sup> to a four-band semi-logarithmic distribution function and derived the following expression for the calculation of the Br<sub>2</sub> absorption spectrum over the wavelength region 200–650 nm

$$\begin{aligned}\sigma(298 \text{ K}) = & 1.06 \times 10^{-20} \times \exp(-52.3[\ln(223.3/\lambda)]^2) \\ & + 6.19 \times 10^{-19} \times \exp(-108.5[\ln(411.9/\lambda)]^2) \\ & + 3.39 \times 10^{-19} \times \exp(-106.8[\ln(480.2/\lambda)]^2) \\ & + 3.78 \times 10^{-20} \times \exp(-112.0[\ln(549.3/\lambda)]^2)\end{aligned}$$

where  $\lambda$  is the wavelength in nm (vacuum) and  $\sigma$  is the absorption cross section in cm<sup>2</sup> molecule<sup>-1</sup>. The recommended absorption cross sections calculated using this expression are listed in Table 4G-2. The results of Maric et al.<sup>10</sup> have been confirmed, in general, in a subsequent study by Hubinger and Nee,<sup>6</sup> who reported absorption cross sections for the wavelength range 190–600 nm. The Hubinger and Nee cross sections values that are below 10<sup>-21</sup> cm<sup>2</sup> molecule<sup>-1</sup>, i.e., between 260 and 340 nm, differ from the parameterized data of Maric et al.<sup>10</sup> and should be considered as upper limits.

The temperature dependence of the absorption spectrum has been measured by Acton et al.<sup>1</sup> (293–906 K) and Passchier et al.<sup>12</sup> (298–713 K). These studies report a decrease of the cross sections around the absorption maximum, between ~380 and ~500 nm, and an increase in the short and long wavelength tails with increasing temperature.

*Photolysis Quantum Yield and Product Studies:* Photodissociation of Br<sub>2</sub> leads to the formation of Br atoms in the ground Br(<sup>2</sup>P<sub>3/2</sub>) and excited Br<sup>\*</sup>(<sup>2</sup>P<sub>1/2</sub>) states. A few studies have been performed to establish the relative quantum yields of (Br + Br) and (Br + Br<sup>\*</sup>) at various photolysis wavelengths. Petersen and Smith<sup>13</sup>

found the yield of Br\* atoms to increase from 0.4 to 0.89 from 444 to 510 nm and decrease at longer wavelengths to a value of ~0.4 at 530 nm. Lindeman and Wiesenfeld<sup>9</sup> observed the relative quantum yield (Br + Br\*) to increase from 0.07 at 434 nm to 0.64 at 482 nm and then to decrease to 0.57 at 511 nm. Haugen et al.<sup>4</sup> determined the relative quantum yield (Br + Br\*) to increase from 0.44 at 445 nm to 0.87 at 500 nm followed by a decrease to 0.40 at 530 nm. Cooper et al.<sup>2</sup> measured the relative (Br + Br\*) yield to be zero in the range 360 to 430 nm and to increase at longer wavelengths to 0.79 at 580 nm; at 260 nm they observed (Br + Br\*) to be dominant. Jee et al.<sup>7,8</sup> measured the relative yield of the photodissociation channel into (Br + Br\*) at 234 nm to be unity and at 265 nm to be 0.96. Zaraga et al.<sup>19</sup> calculated the zero pressure predissociation quantum yield from high resolution spectroscopic studies in the banded region ( $B\ ^3\Pi(0_u^+)$  state) overlapping a continuum at 588 nm to be near unity.

**Table 4G-2. Recommended Absorption Cross Sections of Br<sub>2</sub> at 298 K**

## G2. HBr (hydrogen bromide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of HBr, hydrogen bromide, at wavelengths >180 nm consists of a continuous band with a maximum near 178 nm and monotonically decreasing absorption cross sections that have been measured out to 270 nm. At shorter wavelengths the spectrum shows a large number of strong sharp bands that extend to 105 nm.

The room temperature absorption cross sections of HBr have been measured in a number of studies as outlined in Table 4G-3. The absorption cross sections near the maximum of the absorption band reported by Nee et al.<sup>7</sup> and Huebert and Martin<sup>6</sup> are in good agreement,  $2.4 \times 10^{-18}$  and  $2.7 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ , respectively. The values reported by Romand<sup>12</sup> and Roxlo and Mandl<sup>13</sup> are substantially lower,  $2 \times 10^{-18}$  and  $1.4 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ , respectively. The cross section at 193 nm reported by Vaghjiani<sup>14</sup> and Barone et al.<sup>1</sup> are consistent with the absorption spectra reported by Nee et al.<sup>7</sup> and Huebert and Martin.<sup>6</sup> The cross sections at 184.9 nm measured by Ravishankara et al.<sup>10</sup> and Barone et al.<sup>1</sup> fall between those reported by Nee et al.<sup>7</sup> and Huebert and Martin.<sup>6</sup> The cross section at 184.9 nm measured by Okabe<sup>8</sup> lies between those of Goodeve and Taylor<sup>5</sup> and Romand.<sup>12</sup> The recommended values in Table 4G-4 were derived as follows: the spectra of Goodeve and Taylor,<sup>5</sup> Romand,<sup>12</sup> Huebert and Martin,<sup>6</sup> and Nee et al.<sup>7</sup> have been scaled to  $2.21 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  at 184.9 nm, which is the mean of the values reported by Okabe,<sup>8</sup> Ravishankara et al.,<sup>10</sup> and Barone et al.<sup>1</sup>; the scaled spectra have been averaged, the recommended cross sections for the range 152–168 nm are those of Romand<sup>12</sup> and Nee et al.,<sup>7</sup> for the range 170–180 nm those of Romand,<sup>12</sup> Huebert and Martin,<sup>6</sup> and Nee et al.<sup>7</sup> and for the range 182–230 nm those of Goodeve and Taylor,<sup>5</sup> Romand,<sup>12</sup> Huebert and Martin,<sup>6</sup> and Nee et al.<sup>7</sup>

**Table 4G-3. Summary of HBr UV Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength Range (nm)
Goodeve and Taylor <sup>5</sup>	1935	298	182–286
Romand <sup>12</sup>	1949	298	139–228
Huebert and Martin <sup>6</sup>	1968	297	170–230
Bridges and White <sup>3</sup>	1973	298	214
Okabe <sup>8</sup>	1977	296	240–270
Ravishankara et al. <sup>10</sup>	1979	298	184.9
Roxlo and Mandl <sup>13</sup>	1980	298	170–230
Okabe <sup>9</sup>	1983	296	184.9
Brion et al. <sup>4</sup>	1985	298	30–177
Nee et al. <sup>7</sup>	1986	298	105–238
Vaghjiani <sup>14</sup>	1993	296	193
Barone et al. <sup>1</sup>	1994	298	184.9, 193.0

*Photolysis Quantum Yield and Product Studies:* The branching fraction for the formation of excited Br\*( $^2P_{1/2}$ ) atoms was determined by Regan et al.<sup>11</sup> in the wavelength range 201–253 nm to vary between 0.15 and 0.23. Baumfalk et al.<sup>2</sup> obtained a Br\* branching fraction, Br\*( $^2P_{1/2}$ )/(Total Br), of  $0.20 \pm 0.03$  at 243 nm and  $0.18 \pm 0.03$  at 193 nm.

### G3. BrO (bromine monoxide radical)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The BrO (bromine monoxide) radical has a UV absorption spectrum in the 290–380 nm range, with vibrational band structure, which is attributed to the A <sup>2</sup>P<sub>3/2</sub> ← X <sup>2</sup>P<sub>3/2</sub> transition. The spectrum measured by Wilmouth et al.<sup>11</sup> (0.5 nm) is shown in Figure 4G-1 and laboratory measurements are summarized in Table 4G-5. The absorption spectrum has been measured and cross sections determined for several absorption peaks in the studies listed in Table 4G-5, e.g. for the strongest (7,0) band at 338.5 nm and the (11,0) and (12,0) bands at 320.8 nm and 317.3 nm.

**Table 4G-5. Summary of BrO Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength Range (nm)	Resolution (nm)
Clyne and Cruse <sup>2</sup>	1970	293	338.3	0.15
Basco and Dogra <sup>1</sup>	1971	298	320.8, 338.3	not given
Cox et al. <sup>3</sup>	1982	298	296–370	0.22
Wahner et al. <sup>9</sup>	1988	228, 243, 298	312–380	0.4
Sander and Friedl <sup>8</sup>	1989	220, 298	338.5	0.06–1.25
Orlando et al. <sup>7</sup>	1991	298	338.5	0.4
Laszlo et al. <sup>6</sup>	1997	295	338.5	0.6
Gilles et al. <sup>5</sup>	1997	204, 222, 237, 252, 273, 298, 329, 369	338.5	0.5
Wheeler et al. <sup>10</sup>	1998	298	338, 317	4 cm <sup>-1</sup>
Wilmouth et al. <sup>11</sup>	1999	298	317–388	1.0 cm <sup>-1</sup>
Wilmouth et al. <sup>11</sup>	1999	228, 298	286–386	10 cm <sup>-1</sup>
Fleischmann et al. <sup>4</sup>	2003	203, 223, 243, 273, 298	300–385	4 cm <sup>-1</sup>

The cross sections are both temperature and resolution dependent, i.e., the peaks of the vibrational bands become greater and the bands sharper with decreasing temperature and at higher resolution. Wilmouth et al.<sup>11</sup> used their absorption spectrum, recorded at 10 cm<sup>-1</sup> resolution, in a combined analysis of the results from Cox et al.,<sup>3</sup> Wahner et al.,<sup>9</sup> Orlando et al.,<sup>7</sup> Laszlo et al.,<sup>6</sup> and Gilles et al.<sup>5</sup> at a common resolution of 0.40 nm (details of this procedure are described in Wilmouth et al.<sup>11</sup>). The vibrational band peak absorption cross sections at 298 ± 2 and 228 ± 2 K obtained in their analysis are listed in Table 4G-6. Absorption cross sections of the spectrum reported by Wilmouth et al.,<sup>11</sup> averaged over 0.5 nm intervals are listed in Table 4G-7.

Absorption cross sections for the rotational peaks of the (7,0) and (12,0) bands were measured at high resolution (1.0 cm<sup>-1</sup>) by Wilmouth et al.<sup>11</sup> to be  $\sigma = 2.17 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup> for the peak of the (7,0) band and  $\sigma = 1.38 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup> for the peak of the (12,0) band.

The (7,0) absorption maximum (338 nm) temperature dependence was measured by Gilles et al.<sup>5</sup> over the range 204–388 K at a resolution of 0.5 nm and given by the expression.

$$\sigma(T)_{338\text{ nm}} = 3.29 - (5.58 \times 10^{-3}) \times T, \text{ in units of } 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$$

*Photolysis Quantum Yield and Product Studies:* Transitions in the A←X system are expected to be dissociative.

#### G4. OBrO (bromine dioxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The visible absorption spectrum of OBrO, bromine dioxide, has been measured in the 400–600 nm region at room temperature by Rowley et al.<sup>4</sup> and Knight et al.,<sup>1</sup> at ~250 K by Miller et al.,<sup>2</sup> and at 273, 298, and 338 K by Rattigan et al.<sup>3</sup> The OBrO spectrum measured by Knight et al. is shown in Figure 4G-2. The spectrum has a highly structured absorption band consisting of a progression of doublets with a maximum intensity near 500 nm and a progression of less intense bands between the doublets. The spectrum was assigned to the C <sup>2</sup>A<sub>2</sub> ← X <sup>2</sup>B<sub>1</sub> electronic transition by Miller et al.<sup>2</sup> who combined *ab initio* calculations of the lowest doublet electronic states of OBrO with Franck-Condon simulations. Knight et al.<sup>1</sup> reported absorption cross section data. The peak positions and cross sections for the vibrational progressions (n,0,0)←(0,0,0) and (n,1,0)←(0,0,0) in Table 4G-8 are taken from Knight et al.<sup>1</sup> Table 4G-9 gives the absorption cross section averages over 1 nm intervals of the spectrum reported by Knight et al.<sup>1</sup> (0.66 nm resolution).

*Photolysis Quantum Yield and Product Studies:* No quantum yields are available but theoretical calculations by Vetter et al.<sup>5</sup> indicate that photodissociation occurs via the BrO + O(<sup>3</sup>P) channel because of a large transition dipole moment for the C <sup>2</sup>A<sub>2</sub> ← X <sup>2</sup>B<sub>1</sub> transition. Photodissociation into Br + O<sub>2</sub> occurs via the 1<sup>2</sup>B<sub>2</sub> state and is less probable and therefore less important.

## G5. Br<sub>2</sub>O (dibromine monoxide)

[Back to Index](#)

Br <sub>2</sub> O + hν	→ Br + BrO	128 kJ mol <sup>-1</sup>	938 nm	(1)
	→ Br <sub>2</sub> + O	173 kJ mol <sup>-1</sup>	693 nm	(2)
	→ Br + Br + O	366 kJ mol <sup>-1</sup>	327 nm	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of Br<sub>2</sub>O, dibromine monoxide, has been measured at room temperature by Orlando and Burkholder<sup>3</sup> (196–432 nm), Rattigan et al.<sup>4</sup> (240–515 nm), and Deters et al.<sup>2</sup> (208–444 nm). The spectrum exhibits a strong narrow band at wavelengths <220 nm with a maximum at 200 nm, a weaker and broader band extending from 250 nm to about 460 nm with a maximum at 313 nm and a shoulder near 350 nm, and two weak bands at 460–580 nm and 580–750 nm with maxima at ~520 nm and ~665 nm. There is good agreement between the various data sets in the wavelength region <380 nm where the data of Orlando and Burkholder<sup>3</sup> and Deters et al.<sup>2</sup> are nearly identical and those of Rattigan et al.<sup>4</sup> are smaller by ~10% below 250 nm and above 290 nm and smaller by up to ~25% in the region of the absorption

minimum near 270 nm. Large discrepancies exist between the data sets at wavelengths >380 nm. The absorption cross sections reported by Orlando and Burkholder<sup>3</sup> and Deters et al.<sup>2</sup> decrease at longer wavelengths to values  $\leq 1 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  whereas the values reported by Rattigan et al.<sup>4</sup> show a decrease between 400 and 470 nm and evidence for another absorption band at longer wavelengths. The cutoff at 440 nm of the absorption spectrum reported by Orlando and Burkholder<sup>3</sup> is a result of the assumption that the absorbance of Br<sub>2</sub>O is zero at wavelengths >440 nm. The correction procedure used by Rattigan et al.<sup>4</sup> taking the vibrational structure of the Br<sub>2</sub> spectrum into account resulted in appreciable absorption for Br<sub>2</sub>O at wavelengths above 440 nm. The recommended cross sections in Table 4G-10 are the data from Orlando and Burkholder<sup>3</sup> at 196 and 200 nm, the mean of the data from Orlando and Burkholder<sup>3</sup> and Deters et al.<sup>2</sup> for the region 210–230 nm, and the mean of the data from Orlando and Burkholder,<sup>3</sup> Deters et al.,<sup>2</sup> and Rattigan et al.<sup>4</sup> for the region 240–400 nm. No recommendation is given for wavelengths >400 nm.

*Photolysis Quantum Yield and Product Studies:* By analogy to Cl<sub>2</sub>O the predominate photodissociation channel is expected to be Br + BrO. Burkholder<sup>1</sup> measured the BrO yield at 308 nm to be near unity.

## G6. HOBr (hypobromous acid)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of HOBr, hypobromous acid, has been measured by Orlando and Burkholder<sup>8</sup> (240–404 nm), Deters et al.<sup>3</sup> (250–400 nm), Benter et al.<sup>2</sup> (234–390 nm), Rattigan et al.<sup>9</sup> (240–510 nm), and Ingham et al.<sup>5</sup> (260–600 nm). Orlando and Burkholder,<sup>8</sup> Deters et al.,<sup>3</sup> and Benter et al.<sup>2</sup> observed two absorption bands with maxima near 284 and 351 nm. The reported spectra agree reasonably well in their wavelength dependence with a sharp decrease in cross section at wavelengths greater than 400 nm. In contrast, the cross sections reported by Rattigan et al.<sup>9</sup> and Ingham et al.<sup>5</sup> are roughly 50% greater between 300 and 400 nm. In addition, the spectrum reported by Rattigan et al.<sup>9</sup> has pronounced long wavelength absorption that extends to 520 nm. Ingham et al.<sup>5</sup> report a similar spectrum to Rattigan et al., but with a more prominent absorption band at long wavelength with a maximum at 457 nm. These two studies are consistent with the observations of Barnes et al.,<sup>1</sup> who showed that laser photolysis of HOBr between 440–600 nm gives rise to OH photofragments. The presence of a weak band beyond 400 nm is attributable to the presence of a forbidden transition from the ground electronic to a triplet state as predicted by the *ab initio* calculations of Francisco et al.<sup>4</sup> and Minaev.<sup>7</sup> The differences in the spectral shapes are probably attributable to impurities such as Br<sub>2</sub>O and Br<sub>2</sub>, and/or the use of different Br<sub>2</sub>O cross sections. However, the presence of impurities alone cannot explain the large difference in cross sections at the peak of the absorption bands.

The recommended absorption cross sections in Table 4G-11 are based on the study by Ingham et al.<sup>5</sup> These authors generated HOBr in situ by laser photolytic production of OH in the presence of Br<sub>2</sub>, and determined the HOBr spectrum using a gated diode camera shortly after the pulse, circumventing the problem associated with the presence of the strong absorbing impurity Br<sub>2</sub>O, which was present in previous studies. The calibration of the absorption cross sections was made relative to the cross sections of Br<sub>2</sub>. No recommendation is given for wavelengths <250 nm where the data are uncertain. On the basis of the level of agreement among the available studies, cross section uncertainty factors (2σ) of 1.25 (250–300 nm), 1.5 (300–400 nm), 3 (400–500 nm), and 10 (>500 nm) are estimated for the wavelength ranges given in parenthesis.

The data presented in Table 4G-11 were computed with the following expression taken from Ingham et al.,<sup>5</sup> which is based on a combination of three Gaussian functions, one for each absorption band

$$\sigma(\lambda) = 24.77 \exp\left\{-109.80 \left[\ln\left(\frac{284.01}{\lambda}\right)\right]^2\right\} + 12.22 \exp\left\{-93.63 \left[\ln\left(\frac{350.57}{\lambda}\right)\right]^2\right\} \\ + 2.283 \exp\left\{-242.40 \left[\ln\left(\frac{457.38}{\lambda}\right)\right]^2\right\}$$

where  $\sigma(\lambda)$  is in units of  $10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup> and  $\lambda$  is in nm.

*Photolysis Quantum Yield and Product Studies:* Benter et al.<sup>2</sup> measured quantum yields for HOBr photolysis at 261 and 363 nm (near the band peaks). The observed quantum yield for Br formation at 363 nm was greater than 0.95 and a unity quantum yield for the OH + Br product channel is recommended. No evidence for the O + HBr product channel was observed. The laser photofragment study of Barnes et al.<sup>1</sup> claimed that OH was the major photolysis product at wavelengths >400 nm. Lock et al.<sup>6</sup> found that at 490 and 510 nm OH and Br photofragments are in their respective vibrational and spin-orbit ground states.

**G7. BrNO (nitrosyl bromide)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of BrNO, nitrosyl bromide, has been measured at room temperature by Eden et al.<sup>1</sup> (275–550 nm), Houel and van den Bergh<sup>3</sup> (200–800 nm), Uthman et al.<sup>5</sup> (189–300 nm), Hippler et al.<sup>2</sup> (266 nm), and Maloney and Palmer<sup>4</sup> (270 nm). The spectrum exhibits four absorption bands between 200 and 800 nm, a strong band between 190 and 290 nm with the maximum at ~213 nm, a weaker band between 290 and 600 nm with the maximum at 338 nm and a shoulder near 420 nm, and a still weaker band between 600 and 800 nm with the maximum at 708 nm. The absorption cross sections from these studies are in good agreement (after correction of an error in Maloney and Palmer<sup>4</sup>). The recommended absorption cross sections in Table 4G-12 are from Uthman et al.<sup>5</sup> for the region 189–300 nm and the cross sections at 338, 416, and 708 nm reported by Houel and van den Bergh<sup>3</sup>.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**G8. cis-BrONO (bromine nitrite)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of *cis*-BrONO, bromine nitrite, has been measured in the temperature range 228–296 K by Burkholder and Orlando<sup>1</sup> (200–365 nm). The spectrum exhibits a strong absorption band between 200 and 270 nm with a maximum at 228 nm and a broader and weaker band between 270 and 364 nm with a maximum at 316 nm. The shape of the *cis*-BrONO spectrum was

independent of temperature over the 228–296 K range to within the uncertainty of the measurements. The results from Burkholder and Orlando<sup>1</sup> are recommended and listed in Table 4G-13.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

#### G9. BrNO<sub>2</sub> (nitryl bromide)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Scheffler et al.<sup>2</sup> measured the room temperature absorption spectrum of BrNO<sub>2</sub>, nitryl bromide, over the wavelength range 185–530 nm. The spectrum consists of several overlapping electronic transitions with a strong band in the actinic region (>200 nm). The recommended absorption cross sections in Table 4G-14 are taken from Scheffler et al.<sup>2</sup> between 185 and 430 nm while values at  $\lambda > 430$  nm were obtained from a log-linear fit of the data reported by Scheffler et al. The BrNO<sub>2</sub> spectrum recorded in the Burkholder and Orlando<sup>1</sup> study of *cis*-BrONO was reported to be in good agreement with the Scheffler et al. spectrum.

*Photolysis Quantum Yield and Product Studies:* By analogy with ClNO<sub>2</sub>, the most likely photolysis products are expected to be Br + NO<sub>2</sub>.

**G10. BrONO<sub>2</sub> (bromine nitrate)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of BrONO<sub>2</sub>, bromine nitrate, has been measured at room temperature by Spencer and Rowland<sup>5</sup> (186–390 nm), Burkholder et al.<sup>1</sup> (200–500 nm), and Deters et al.<sup>2</sup> (210–500 nm). The absorption cross sections reported by Burkholder et al.<sup>1</sup> and Deters et al.<sup>2</sup> are nearly identical over the range of spectral overlap. The results of Spencer and Rowland<sup>5</sup> agree to within 10% with those of Burkholder et al.<sup>1</sup> and Deters et al.<sup>2</sup> except for the region between 315 and 350 nm where the Spencer data are higher by 10 to 20%.

The temperature dependence of the absorption spectrum has been measured by Burkholder et al.<sup>1</sup> (200–500 nm) at 220, 250, and 298 K and Deters et al.<sup>2</sup> (210–500 nm) at 230 and 298 K. The temperature dependence of the absorption cross sections is in general weak. Burkholder et al.<sup>1</sup> observed decreasing cross sections with decreasing temperature between 200 and 215 nm and between 230 and 500 nm and a slight increase between 215 and 230 nm. The reported ratio  $\sigma(220\text{ K})/\sigma(298\text{ K})$  has values of ~0.8 to 1.03 between 200 and 235 nm,

a minimum of 0.90 at 260 nm, nearly constant values of ~0.95 between 290 and 370 nm, a minimum of ~0.87 at 430 nm, two maxima of ~0.98 around 445 nm, and decreases to ~0.5 at 500 nm. The measurements of Deters et al.<sup>2</sup> show a similar behavior of  $\sigma(230\text{ K})/\sigma(298\text{ K})$  vs.  $\lambda$  with all values below 1, i.e., a decrease of the cross sections with decreasing temperature is observed over the entire spectrum. Burkholder et al.<sup>1</sup> parameterized the cross section temperature dependence using the expression

$$\sigma(\lambda, T) = \sigma(\lambda, 296\text{ K}) [1 + A_1(\lambda)(T-296) + A_2(\lambda)(T-296)^2]$$

The recommended absorption cross sections and temperature coefficients in Table 4G-15 are taken from Burkholder et al.<sup>1</sup> A cross section uncertainty factor of 1.2 ( $2\sigma$ ), independent of wavelength, is assigned, which encompasses the results from all the room temperature studies.

*Photolysis Quantum Yield and Product Studies:* Photodissociation quantum yields have been measured for photolysis wavelengths between 248 and 355 nm as summarized in Table 4G-16. The quantum yields for NO<sub>3</sub> production were measured by Harwood et al.<sup>3</sup> to be  $\Phi(\text{NO}_3) = 0.28 \pm 0.09$  at 248 nm,  $1.01 \pm 0.35$  at 305 nm and  $0.92 \pm 0.43$  at 352.5 nm. The quantum yields for BrO and Br were also estimated at 248 nm to be  $\Phi(\text{BrO}) \approx 0.5$  and  $\Phi(\text{Br}) \approx 0.5$ . Soller et al.<sup>4</sup> investigated the production of Br, O(<sup>3</sup>P), and BrO from the photolysis of BrONO<sub>2</sub> in the wavelength range 248–355 nm. The quantum yield for the Br atom are  $0.35 \pm 0.08$ ,  $0.65 \pm 0.14$ ,  $>0.62 \pm 0.11$ , and  $0.77 \pm 0.19$  at 248, 266, 308, and 355 nm, respectively. The values for the O(<sup>3</sup>P) atom quantum yields are  $0.66 \pm 0.15$ ,  $0.18 \pm 0.04$ ,  $<0.13 \pm 0.03$ , and  $<0.02$  at 248, 266, 308 and 355 nm, respectively. The measured quantum yields for BrO are  $0.37 \pm 0.12$  at 266 nm and  $0.23 \pm 0.08$  at 355 nm. A total quantum yield  $\Phi_{\text{BrONO}_2}$  of unity is recommended for wavelengths >300 nm with  $\Phi_{\text{Br+NO}_3} = 0.85$  and  $\Phi_{\text{BrO+NO}_2} = 0.15$ . No recommendation is given for wavelengths <300 nm.

**G11. BrCl (bromine chloride)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of BrCl, bromine chloride, has been measured at room temperature by Gray and Style<sup>1</sup> (240–313 nm and 546 nm), Jost<sup>3</sup> (486–548 nm), Seery and Britton<sup>5</sup> (220–510 nm), Maric et al.<sup>4</sup> (200–600 nm), Hubinger and Nee<sup>2</sup> (190–560 nm), and Tellinghuisen<sup>7</sup> (200–600 nm). The spectrum exhibits an absorption band between 190 and 290 nm with a maximum at 230 nm ( $\sigma \approx (6.0\text{-}7.2) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ ) and a stronger band between 290 and 600 nm with the maximum at 375 nm ( $\sigma \approx (3.9\text{-}4.1) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ ) and a shoulder near 470 nm. There is good agreement between the cross section results of the studies except for the values at 289 and 297 nm reported by Gray and Style,<sup>1</sup> which are smaller by a factor of ~2.5 than the rest of the results. The agreement is within 20% for the short wavelength band around 230 nm between the results of Seery and Britton,<sup>5</sup> Maric et al.,<sup>4</sup> and Hubinger and Nee,<sup>2</sup> where Seery and Britton<sup>5</sup> report the highest and Hubinger and Nee<sup>2</sup> the lowest values. There is good agreement, to within ~5–15%, for the stronger band around 375 nm where Seery and Britton<sup>5</sup> and Tellinghuisen<sup>7</sup> report the highest and Hubinger and Nee<sup>2</sup> the lowest cross sections. The discrepancies are larger, up to 50%, in the region of the absorption minimum around 290 nm where Seery and Britton<sup>5</sup> and Hubinger and Nee<sup>2</sup> report the highest cross sections and Tellinghuisen<sup>7</sup> the lowest. Excellent agreement is observed in the long wavelength tail above 450 nm between the data of Maric et al.<sup>4</sup> and Tellinghuisen<sup>7</sup> whereas those from Hubinger and Nee<sup>2</sup> are 50% or more larger and those from Jost<sup>3</sup> are lower by ~20–40%. Maric et al.<sup>4</sup> fit a three-band semi-logarithmic Gaussian distribution function to their 0.2 nm resolution data (200–600 nm) and obtained:

$$\begin{aligned} \sigma(298 \text{ K}) = & 6.52 \times 10^{-20} \times \exp(-54.1 [\ln(227.6/\lambda)]^2) \\ & + 3.86 \times 10^{-19} \times \exp(-97.6 [\ln(372.5/\lambda)]^2) \\ & + 9.99 \times 10^{-20} \times \exp(-66.9 [\ln(442.4/\lambda)]^2) \end{aligned}$$

where  $\lambda$  is the wavelength in nm and  $\sigma$  is the absorption cross section in  $\text{cm}^2 \text{ molecule}^{-1}$ . The recommended absorption cross sections calculated using this expression are listed in Table 4G-17.

A semi-empirical expression based on the theory of Sulzer and Wieland,<sup>6</sup> which describes the temperature and wavelength dependence of an absorption spectrum, was derived by Maric et al.<sup>4</sup> to be

$$\begin{aligned}\sigma(T, \lambda) = & 7.34 \times 10^{-20} \times \tanh^{0.5} \times \exp(-68.6 \times \tanh \times [\ln(227.6/\lambda)]^2) \\ & + 4.35 \times 10^{-19} \times \tanh^{0.5} \times \exp(-123.6 \times \tanh \times [\ln(372.5/\lambda)]^2) \\ & + 1.12 \times 10^{-19} \times \tanh^{0.5} \times \exp(-84.8 \times \tanh \times [\ln(442.4/\lambda)]^2)\end{aligned}$$

where  $\lambda$  is the wavelength in vacuum (200–600 nm),  $\tanh = \tanh(hc\omega_e/2kT) = \tanh(318.8/T)$  (with  $\omega_e = 443.1 \text{ cm}^{-1}$ ), and  $T$  is the temperature (195–300 K).

*Photolysis Quantum Yield and Product Studies:* It is expected that BrCl photodissociates with unit quantum yield.

**Table 4G-17. Recommended Absorption Cross Sections of BrCl at 298 K**

**G12. BrOCl (bromochloromonoxide)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of BrOCl, bromochloromonoxide, was measured at room temperature over the wavelength range 230–390 nm by Burkholder et al.<sup>1</sup> Their results are recommended and given in Table 4G-18.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**G13. CH<sub>3</sub>Br (methyl bromide)**[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption spectrum of CH<sub>3</sub>Br, methyl bromide, has been measured at room temperature by Davidson<sup>1</sup> (205–270 nm), Gordus and Bernstein<sup>5</sup> (204–260 nm), Robbins<sup>10</sup> (174–270 nm), Uthman et al.<sup>12</sup> (200–260 nm), Molina et al.<sup>8</sup> (190–290 nm), Felps et al.<sup>3</sup> (201.6 nm), Man et al.<sup>7</sup> (180–264 nm), and over the temperature range 210–295 K by Gillotay and Simon<sup>4</sup> (180–280 nm). At wavelengths >180 nm and <270 nm, the room temperature values of Gordus and Bernstein,<sup>5</sup> Robbins,<sup>10</sup> Uthman et al.,<sup>12</sup> Molina et al.,<sup>8</sup> Gillotay and Simon,<sup>4</sup> and the values of Davidson<sup>1</sup> at wavelengths >210 nm are in very good agreement, to within 10% and within 2% at the absorption maximum ~201 nm. The value from Felps et al.<sup>3</sup> at 202 nm is lower by ~10% than the other studies. The cross section data of Man et al.,<sup>7</sup> reported graphically, are lower by 20–30% over the entire band in comparison with the other data sets. The recommended absorption cross sections in Table 4G-19 are the mean of the values reported by Gillotay and Simon<sup>4</sup> and Robbins<sup>10</sup> for the range 182–188 nm, the mean of the values reported by Gillotay and Simon,<sup>4</sup> Uthman et al.,<sup>12</sup> and Robbins<sup>10</sup> for the range 190–198 nm, the mean of the values reported by Gillotay and

Simon,<sup>4</sup> Molina et al.,<sup>8</sup> Uthman et al.,<sup>12</sup> and Robbins<sup>10</sup> for the range 200–260 nm, the mean of the values reported by Gillotay and Simon,<sup>4</sup> Molina et al.,<sup>8</sup> and Robbins<sup>10</sup> for the range 262–268 nm; the mean of the values reported by Gillotay and Simon<sup>4</sup> and Molina et al.<sup>8</sup> for the range 270–280 nm, and the data from Molina et al.<sup>8</sup> for the range 285–290 nm. A wavelength independent cross section uncertainty factor of 1.2 ( $2\sigma$ ) is assigned for the recommended wavelength range.

The VUV absorption spectrum at 298 K was measured by Olney et al.<sup>9</sup> (2.8–199 nm) and Locht et al.<sup>6</sup> (50–207 nm). A Lyman- $\alpha$  cross section of  $3.2 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  from the Locht et al. study is recommended with an uncertainty factor of 1.3 ( $2\sigma$ ), which covers the range in the available experimental data.

Gillotay and Simon<sup>4</sup> report a slight temperature dependence in the absorption cross sections for wavelengths >220 nm where the values decrease with decreasing temperature. Gillotay and Simon<sup>4</sup> parameterized the cross sections and the temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and reported calculated values for  $T = 210, 230, 250, 270$ , and  $295 \text{ K}$ . However, the fit parameters given in Gillotay et al. result in a systematic bias in the calculated cross sections at wavelengths greater than 200 nm and a poor fit to their experimental data at shorter wavelengths. A re-fit of their data yielded the  $A_n$  and  $B_n$  parameters below, which are valid for the wavelength range 210–290 nm and temperature range 210–300 K. The re-fit removes the systematic bias and reproduces the experimental data to within 5%, while improving the short wavelength fit although deviations are still significant. This fit is recommended.

A <sub>0</sub> = 7.997	B <sub>0</sub> = 0.457415
A <sub>1</sub> = -0.889724	B <sub>1</sub> = -0.00882996
A <sub>2</sub> = 0.00838084	B <sub>2</sub> = 6.40235 × 10 <sup>-5</sup>
A <sub>3</sub> = -3.03191 × 10 <sup>-5</sup>	B <sub>3</sub> = -2.06827 × 10 <sup>-7</sup>
A <sub>4</sub> = 3.69427 × 10 <sup>-8</sup>	B <sub>4</sub> = 2.51393 × 10 <sup>-10</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for Br and H atom formation in the photodissociation of CH<sub>3</sub>Br were measured at 298 K by Talukdar et al.<sup>11</sup> The quantum yields for Br atom formation were found to be close to unity,  $\Phi(\text{Br}) = 1.05 \pm 0.11$ ,  $1.10 \pm 0.20$ , and  $1.01 \pm 0.16$  at 193, 222, and 248 nm, respectively. The quantum yield for H atom formation in the photolysis at 193 nm was measured to be  $\Phi(\text{H}) = 0.002 \pm 0.001$ , whereas H atoms could not be detected in the photolysis at 222 and 248 nm. Using broadband flash photolysis of CH<sub>3</sub>Br, Ebenstein et al.<sup>2</sup> reported a Br\*(<sup>2</sup>P<sub>1/2</sub>) fractional yield, Br\*(<sup>2</sup>P<sub>1/2</sub>)/(Total Br), of  $0.15 \pm 0.12$ .

#### G14. CH<sub>2</sub>Br<sub>2</sub> (dibromomethane)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of CH<sub>2</sub>Br<sub>2</sub>, dibromomethane, has been measured at room temperature by Molina et al.<sup>3</sup> (200–300 nm), Gillotay et al.<sup>1,2</sup> (174–290 nm), and Mössinger et al.<sup>4</sup> (215–300 nm). The absorption cross sections are in good agreement in the range 200–255 nm, to within 10%, and at 275 nm they are within 30%. The recommended absorption cross sections in Table 4G-20 are the values from Gillotay et al.<sup>1,2</sup> in the region 174–198 nm, the mean of the values reported by Molina et al.<sup>3</sup> and Gillotay et al.<sup>1,2</sup> for the range 200–215 nm, the mean of the values reported by the three groups for the range 220–290 nm, and values from Mössinger et al.<sup>4</sup> for the range 295–300 nm. On the basis of the level of agreement among the available studies, cross section uncertainty factors (2σ) of 1.05 (200–250 nm), 1.1 (250–270 nm), and 1.2 (270–300 nm) are estimated for the wavelength ranges given in parenthesis.

The absorption spectrum temperature dependence was measured by Gillotay et al.<sup>1,2</sup> (174–290 nm) over the temperature range 210–295 K and Mössinger et al.<sup>4</sup> (215–300 nm) over the range 250–348 K. The absorption cross sections decrease at wavelength >~235 nm and increase between 235 and 207 nm with decreasing temperature. At shorter wavelengths, Gillotay et al.<sup>1,2</sup> report a slight increase in the cross sections in the range 175–189 nm and a slight decrease around the maximum near 200 nm. Gillotay et al.<sup>1,2</sup> parameterized the cross sections and the temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, which are valid for the wavelength range 210–290 nm and temperature range 210–300 K are given below.

$$\begin{array}{ll}
 A_0 = -70.211776 & B_0 = 2.899280 \\
 A_1 = 1.940326 \times 10^{-1} & B_1 = -4.327724 \times 10^{-2} \\
 A_2 = 2.726152 \times 10^{-3} & B_2 = 2.391599 \times 10^{-4} \\
 A_3 = -1.695472 \times 10^{-5} & B_3 = -5.807506 \times 10^{-7} \\
 A_4 = 2.500066 \times 10^{-8} & B_4 = 5.244883 \times 10^{-10}
 \end{array}$$

Mössinger et al.<sup>4</sup> parameterized their cross section data using the expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda) (T - 298)$$

for the ranges 215–300 nm and 250–348 K. The parameterizations given by Gillotay et al.<sup>1,2</sup> and Mössinger et al.<sup>4</sup> yield cross sections that agree at 250 K to within 5% in the range 215–265 nm and to within 10% in the range 270–285 nm. The B(λ) coefficients from Mössinger et al.<sup>4</sup> are given in Table 4G-20 and recommended for use in model calculations.

*Photolysis Quantum Yield and Product Studies:* It is expected that photolysis will rupture the C-Br bond with unity quantum yield.

## G15. CHBr<sub>3</sub> (tribromomethane, bromoform)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption spectrum of CHBr<sub>3</sub>, tribromomethane (bromoform), has been measured by Gillotay et al.<sup>3</sup> (170–310 nm, 240–295 K), Moortgat et al.<sup>4</sup> (286–362 nm, 256–296 K), and Papanastasiou et al.<sup>5</sup> (300–345 nm, 260–330 K). The agreement in the cross sections reported in these studies

at wavelengths less than 310 nm is very good. Moortgat et al. reported possible complications to their measurements at the longer wavelengths due to the possible presence of impurities as well as optical artifacts arising from adsorption of CHBr<sub>3</sub> on the cell windows. The Papanastasiou et al. study addressed these potential complications in their cavity ring-down spectroscopy measurements, while also addressing contributions from Rayleigh scattering. The recommended cross sections in Table 4G-21 are the values from Gillotay et al. for the range 170–258 nm and for wavelengths greater than 258 nm from the spectrum parameterization of Papanastasiou et al. given below.

The absorption cross sections increase around the three absorption maxima in the ranges 178–189 nm, 194–208 nm, and 208–234 nm, and decrease at wavelengths <179 nm, over the range 189–194 nm, and >235 nm with decreasing temperature. Gillotay et al.<sup>3</sup> parameterized the cross sections and the temperature dependence using an empirical polynomial expansion

$$\log_{10}(\sigma(\lambda, T)) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated values for 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, which are valid for the wavelength range 240–310 nm and temperature range 210–300 K are given below.

$$\begin{array}{ll} A_0 = -110.2782 & B_0 = -1.5312 \times 10^{-1} \\ A_1 = 1.0281 & B_1 = 1.6109 \times 10^{-3} \\ A_2 = -3.6626 \times 10^{-3} & B_2 = -5.8075 \times 10^{-6} \\ A_3 = 4.1226 \times 10^{-6} & B_3 = 7.2893 \times 10^{-9} \end{array}$$

Moortgat et al.<sup>4</sup> parameterized their data using the expression

$$\sigma(\lambda, T) = \exp [ (0.06183 - 0.000241 \lambda) (273 - T) - (2.376 + 0.14757 \lambda) ]$$

for the wavelength range 290–340 nm and temperature range 210–300 K.

Papanastasiou et al. parameterized the CHBr<sub>3</sub> spectrum using their experimental data and the data from Gillotay et al. and Moortgat et al. between 260–310 nm using the expression

$$\log_{10}(\sigma(\lambda, T)) = \sum A_n \lambda^n + (296 - T) \times \sum B_n \lambda^n$$

The obtained parameters are

i	A <sub>i</sub>	B <sub>i</sub>
0	-32.6067	0.1582
1	0.10308	-0.0014758
2	$6.39 \times 10^{-5}$	$3.8058 \times 10^{-6}$
3	$-7.7392 \times 10^{-7}$	$9.187 \times 10^{-10}$
4	$-2.2513 \times 10^{-9}$	$-1.0772 \times 10^{-11}$
5	$6.1376 \times 10^{-12}$	—

and the parameterization is valid over the wavelength range 260–345 nm for temperatures in the range 260–330 K. This parameterization is recommended, while the Gillotay et al. parameterization is recommended for wavelengths <260 nm. A cross section uncertainty factor (2σ) of 1.2 (330–345 nm) and 1.1 (240 to <330 nm) is assigned to the room temperature spectrum.

The VUV absorption spectrum was measured by Causley and Russell<sup>2</sup> (112–190 nm) and the absorption cross section at Lyman-α was measured by Vasta and Volpp<sup>7</sup> at 298 K. A Lyman-α cross section of  $7.1 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  from the direct study of Vasta and Volpp is recommended. There is good agreement between these two studies at Lyman-α and an uncertainty factor of 1.1 (2σ) is assigned.

**Photolysis Quantum Yield and Product Studies:** The quantum yield for the formation of Br atoms were determined by Bayes et al.<sup>1</sup> between 266 and 324 nm. In the wavelength range 303–306 nm, the Br atom quantum yield is unity within experimental error. At longer wavelengths, the quantum yield decreases to 0.76 at 324 nm. Bayes et al.<sup>1</sup> claim that the lower than unity quantum yield may be due to systematic errors in the recommended absorption cross sections used in their data analysis. Their Br atom quantum yields in the wavelength range 300 to 324 nm would be greater and would encompass unity within their state uncertainty with the cross section data from Papanastasiou et al. Support for a unity quantum yield at λ > 300 nm comes from theoretical calculations by Peterson and Francisco.<sup>6</sup> At 266 nm, the Br atom quantum yield is  $0.76 \pm 0.03$ , indicating that another photodissociation channel becomes important. Xu et al.<sup>8</sup> measured atomic Br and molecular Br<sub>2</sub> by TOF mass spectrometry from bromoform photolysis at 234 and 267 nm and report evidence for the formation of CHBr + Br<sub>2</sub>. Xu et al.<sup>8</sup> report Φ(Br) = 0.74 and Φ(Br<sub>2</sub>) = 0.26 for 234

nm photolysis and  $\Phi(\text{Br}) = 0.84$  and  $\Phi(\text{Br}_2) = 0.16$  for 267 nm photolysis. A Br atom quantum yield of unity for wavelengths  $>300$  nm is recommended.

## G17. C<sub>2</sub>H<sub>5</sub>Br (bromoethane)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of C<sub>2</sub>H<sub>5</sub>Br, bromoethane, was measured at 295 K over the wavelength range 200–260 nm by Zhang et al.<sup>2</sup> In this wavelength range the spectrum shows part of an absorption band with a maximum cross section of  $\sim 6 \times 10^{-19}$  cm<sup>2</sup> at  $\sim 200$  nm. The cross section at 200 nm reported by Porret and Goodeve<sup>1</sup> is  $\sim 10\%$  less than in the Zhang et al. spectrum. The recommended absorption cross sections in Table 4G-23 are estimated from a figure in Zhang et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## G20. CH<sub>2</sub>ClBr (Halon-1011, chlorobromomethane)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of CH<sub>2</sub>ClBr, chlorobromomethane (Halon-1011), has been measured at room temperature by Cadman and Simons<sup>1</sup> (210–260 nm) and Orkin et al.<sup>3</sup> (187–290 nm). The cross section data from Cadman and Simons,<sup>1</sup> reported in graphical form, are up to 20% less than the data from Orkin et al.<sup>3</sup> The recommended absorption cross sections in Table 4G-26 are taken from Orkin et al.<sup>3</sup>

**Photolysis Quantum Yield and Product Studies:** Quantum yields for Br (<sup>2</sup>P<sub>3/2</sub>) and Br\* (<sup>2</sup>P<sub>1/2</sub>) atom formation in the photolysis of CH<sub>2</sub>ClBr at 193 and 242 nm and 248, 261.5, and 266.7 nm have been measured by Zou et al.<sup>4</sup> and McGivern et al.,<sup>2</sup> respectively. The reported values are given here.

	193 nm	234 nm	248.5 nm	261.5 nm	266.7 nm
Φ(Br ( <sup>2</sup> P <sub>3/2</sub> ))	0.82 ± 0.10	0.80 ± 0.10	0.86 ± 0.10	0.84 ± 0.10	0.91 ± 0.10
Φ(Br* ( <sup>2</sup> P <sub>1/2</sub> ))	0.18 ± 0.10	0.20 ± 0.10	0.14 ± 0.10	0.16 ± 0.10	0.09 ± 0.10

## G21. CHClBr<sub>2</sub> (Halon-1012, chlorodibromomethane)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of CHClBr<sub>2</sub>, chlorodibromomethane (Halon-1012), has been measured at room temperature by Ibuki et al.<sup>2</sup> (106–200 nm, presented graphically) and Taketani et al.<sup>5</sup> (193.3 nm) and at 240, 261, and 296 K by Bilde et al.<sup>1</sup> (200–310 nm). Two overlapping absorption bands are apparent at wavelengths >200 nm with maxima near 206 nm and 240 nm. The peak cross sections of these bands at 240 K are approximately 10% greater than at room temperature. In the long wavelength tail of the spectrum, the cross sections decrease with decreasing temperature, the room temperature cross section at 270 nm being ~15% greater than at 240 K. The recommended absorption cross sections in Table 4G-27 are from Bilde et al.<sup>1</sup> (reported at 1 nm intervals). Taketani et al.<sup>5</sup> reported a value of 304 × 10<sup>-20</sup> cm<sup>2</sup> molecule<sup>-1</sup> at 193.3 nm.

*Photolysis Quantum Yield and Product Studies:* Quantum yields for dissociation have been reported by Tzeng et al.<sup>6</sup> (193 and 248 nm), McGivern et al.<sup>4</sup> (248–268 nm), Zou et al.<sup>7</sup> (193–242 nm), Lee et al.<sup>3</sup> (234 nm), and Taketani et al.<sup>5</sup> (193.3 nm). In the range 248–262 nm, CHClBr<sub>2</sub> undergoes C-Br bond rupture exclusively, whereas in the range 193–242 nm it dissociates predominantly via C-Br bond rupture with a minor contribution from C-Cl bond rupture. The relative quantum yield for ground state Br(<sup>2</sup>P<sub>3/2</sub>) varies from 0.80 to 0.90 for photolysis in the range 193 to 267 nm.

## G22. $\text{CHCl}_2\text{Br}$ (Halon–1021, dichlorobromomethane)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of  $\text{CHCl}_2\text{Br}$ , dichlorobromomethane (Halon–1021), has been measured at room temperature by Ibuki<sup>3</sup> (106–200 nm, presented graphically), Cadman and Simons<sup>2</sup> (201–270 nm, presented graphically), and Bilde et al.<sup>1</sup> (200–320 nm). Cadman and Simons<sup>2</sup> cross section data agree to within 15% with the room temperature cross section results from Bilde et al.,<sup>1</sup> however, the absorption maximum is shifted to lower wavelengths. The recommended absorption cross sections in Table 4G-28 are taken from Bilde et al.<sup>1</sup>

Bilde et al.<sup>1</sup> (200–320 nm) reported absorption spectrum measurements at 253, 273, and 298 K. A decrease of the absorption cross sections with decreasing temperature was observed over the entire wavelength range of their measurements. The cross section at 220 nm is ~6% lower at 253 K than at room temperature. A stronger temperature dependence was observed at longer wavelengths, the room temperature cross section at 320 nm being about four times larger than at 253 K.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

### G23. CCl<sub>3</sub>Br (Halon–1031, trichlorobromomethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of CCl<sub>3</sub>Br, trichlorobromomethane (Halon–1031), has been measured at room temperature by Cadman and Simons<sup>1</sup> (207–305 nm), Sidebottom et al.<sup>6</sup> (365 nm), Roxlo and Mandl<sup>4</sup> (170–230 nm), Ibuki et al.<sup>2</sup> (105–198 nm), and Seccombe et al.<sup>5</sup> (50–200 nm). The absorption spectrum has a strong absorption band between 170 and 220 nm with the maximum near 185 nm and  $\sigma \approx (1.1\text{--}1.4) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  with a shoulder in the range 220–305 nm. The recommended absorption cross sections in Table 4G-29 for the wavelength region 235–305 nm have been read at 5 nm intervals from a figure in the paper of Cadman and Simons<sup>1</sup> and the value for 365 nm was reported Sidebottom et al.<sup>6</sup>

*Photolysis Quantum Yield and Product Studies:* Product quantum yields were studied at 365 nm by Sidebottom et al.<sup>6</sup> They report evidence that Br + CCl<sub>3</sub> are the primary products and the yields are pressure and temperature dependent. Quantum yields for Br\*(<sup>2</sup>P<sub>1/2</sub>) atom formation in the photolysis at 234 and 265 nm were reported to be  $0.31 \pm 0.01$  and  $0.68 \pm 0.02$ , respectively, by Jung et al.<sup>3</sup>

#### G24. $\text{CHF}_2\text{Br}$ (Halon-1201, difluorobromomethane)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{CHF}_2\text{Br}$ , difluorobromomethane (Halon-1201), has been measured at room temperature by Davidson<sup>1</sup> (207–255 nm), Talukdar et al.<sup>4</sup> (190–280 nm), Gillotay et al.<sup>2</sup> (166–267 nm), and Orkin and Kasimovskaya<sup>3</sup> (190–280 nm). Gillotay et al.<sup>2</sup> carried out measurements at 210–295 K over the wavelength range 166–267 nm and report smoothed calculated cross sections for 210, 230, 250, 270, and 295 K. The results of Davidson,<sup>1</sup> Orkin and Kasimovskaya,<sup>3</sup> and Gillotay et al.<sup>2</sup> are in excellent agreement at wavelengths <240 nm. The values from Gillotay et al.<sup>2</sup> are increasingly smaller (by up to about 40% at 260 nm) and those of Davidson<sup>1</sup> are smaller (by up to about 30% at 250 nm) than the values reported by Orkin and Kasimovskaya.<sup>3</sup> The results of Talukdar et al.,<sup>4</sup> who report a spectrum in graphical form with extrapolated values out to 360 nm, appear to be in agreement with the results of Orkin and Kasimovskaya.<sup>3</sup> The recommended absorption cross sections in Table 4G-30 are the values from Gillotay et al.<sup>2</sup> at the centers of the 500  $\text{cm}^{-1}$  intervals between 168 and 188 nm and the values from Orkin and Kasimovskaya<sup>3</sup> in the region 190–280 nm.

An increase in the absorption cross sections around the absorption peak (168–215 nm) and a decrease at wavelengths >215 nm with decreasing temperature (295–210 K) was reported by Gillotay et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption spectrum of CF<sub>2</sub>Br<sub>2</sub>, difluorodibromomethane (Halon–1202), has been measured at room temperature by Davidson<sup>2</sup> (215–290 nm), Walton<sup>15</sup> (200–310 nm), Molina et al.<sup>8</sup> (190–340 nm), Orkin and Kasimovskaya<sup>9</sup> (190–320 nm), Gillotay and Simon<sup>4</sup> (170–304 nm), Burkholder et al.<sup>1</sup> (190–320 nm), and Papanastasiou et al.<sup>10</sup> (300–350 nm). The study by Papanastasiou et al. reported absorption cross section data in the long wavelength region that were corrected for Rayleigh scattering, which is most important at the longest wavelengths. The room temperature cross section data, except those of Walton,<sup>15</sup> are in good agreement, better than 10%, over the wavelength range 190–300 nm. At the absorption maximum near 226 nm, the data of Davidson<sup>2</sup> and Molina et al.<sup>8</sup> are the highest and lowest, respectively. At wavelengths >300 nm, the values from Orkin and Kasimovskaya,<sup>9</sup> Burkholder et al.,<sup>1</sup> and Papanastasiou et al. agree to within 15%, whereas those of Molina et al.<sup>8</sup> are larger with the difference increasing with increasing wavelength, up to ~200% at 320 nm and ~660% at 340 nm. The recommended absorption cross sections in Table 4G-31 are the values from Gillotay and Simon<sup>4</sup> in the region 170–188 nm, the mean of the values reported by Gillotay and Simon,<sup>4</sup> Orkin and Kasimovskaya,<sup>9</sup> and Burkholder et al.<sup>1</sup> for the wavelength range 190–264 nm, and for the wavelength range 266–350 nm from the parameterization given by Papanastasiou et al. (see below). Uncertainty factors (2σ) for the room temperature absorption cross sections are estimated to be 1.05 for the wavelength range 180 to 230 nm, 1.1 for the wavelength range 230 to 280 nm, and 1.2 for wavelengths in the range 280 to 350 nm. The uncertainty factors encompass the range of the data used to develop the recommendation.

The VUV absorption spectrum at room temperature has been measured Doucet et al.<sup>3</sup> (60–220 nm) and Seccombe et al.<sup>11</sup> (55–175 nm). The reported spectra show some systematic discrepancies in their wavelength dependence, although the two studies are in reasonable agreement at Lyman-α, 121.567 nm. The high-resolution σ(Lyman-α, 298 K) measurement of Seccombe et al.,  $10 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ , is recommended with an uncertainty factor of 1.5 (2σ).

The absorption spectrum temperature dependence was measured by Gillotay and Simon<sup>4</sup> (170–304 nm) over the range 210–295 K, Burkholder et al.<sup>1</sup> (190–320 nm) over the range 210–296 K, and Papanastasiou et al. (300–325 nm) over the range 210–296 K. The absorption cross sections increase at the absorption peaks, near 190 and 225 nm, and decrease at wavelengths >240 nm and <177 nm with decreasing temperature. Gillotay and Simon<sup>4</sup> observed a systematic temperature behavior with an increase in the peak cross section at ~225 nm of  $\sim 9 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  per 20 K decrease in temperature. Burkholder et al.<sup>1</sup> observed a less pronounced temperature behavior below 250 K with the peak cross section at 210 K that is 5% lower than that observed by Gillotay and Simon<sup>4</sup> (the room temperature cross sections from these two studies are nearly identical). Different empirical parameterizations for the temperature dependence of the absorption cross section were proposed. Gillotay and Simon<sup>4</sup> used a polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated values for 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, which are valid for the wavelength range 222–304 nm and temperature range 210–300 K are as follows. This parameterization is recommended for wavelengths in the range 222 nm < λ < 266 nm.

$A_0 = -206.2$	$B_0 = 1.0460 \times 10^{-1}$
$A_1 = 2.3726$	$B_1 = -1.4124 \times 10^{-3}$
$A_2 = -1.0527 \times 10^{-2}$	$B_2 = 6.9015 \times 10^{-6}$
$A_3 = 1.9239 \times 10^{-5}$	$B_3 = -1.5164 \times 10^{-8}$
$A_4 = -1.2242 \times 10^{-8}$	$B_4 = 1.3990 \times 10^{-11}$

Burkholder et al.<sup>1</sup> used the expression

$$\ln \sigma(\lambda, T) = (\sum A_i (\lambda - 268.7998)^i) (1 + (296 - T) \sum B_i (\lambda - 268.7998)^i)$$

and reported the following  $A_i$  and  $B_i$  parameters for the wavelength range 235–260 nm and temperature range 210–296 K.

$A_0 = -44.42756$	$B_0 = 1.481886 \times 10^{-4}$
$A_1 = -1.464955 \times 10^{-1}$	$B_1 = 6.77182 \times 10^{-6}$
$A_2 = -5.692188 \times 10^{-4}$	$B_2 = 1.154347 \times 10^{-7}$
$A_3 = 1.155366 \times 10^{-5}$	$B_3 = -2.77145 \times 10^{-11}$
$A_4 = -1.399502 \times 10^{-7}$	$B_4 = -6.619515 \times 10^{-11}$

Burkholder et al.<sup>1</sup> also report a parameterization for cross sections extrapolated out to 400 nm

$$\ln \sigma(\lambda, T) = (\sum A_i (\lambda - 301.0104)^i) (1 + (296 - T) \sum B_i (\lambda - 301.0104)^i)$$

with the following parameters.

$A_0 = -49.50456$	$B_0 = 3.616315 \times 10^{-4}$
$A_1 = -1.633525 \times 10^{-1}$	$B_1 = 5.534952 \times 10^{-6}$
$A_2 = 5.170758 \times 10^{-6}$	$B_2 = -1.997903 \times 10^{-8}$
$A_3 = 4.332654 \times 10^{-6}$	$B_3 = -9.234512 \times 10^{-11}$
$A_4 = -3.899051 \times 10^{-8}$	$B_4 = 1.776346 \times 10^{-12}$

Note: In the Burkholder et al.<sup>1</sup> paper, the parameterization equation is written in terms of  $\log_{10}(\sigma(\lambda, T))$  but the correct expression should be given in terms of  $\ln(\sigma(\lambda, T))$ , as given here.

The recommended spectrum parameterization for wavelengths >264 nm is taken from the Papanastasiou et al. study, which accounted for Rayleigh scattering that was significant for wavelengths >300 nm. They used the same empirical expression used in the Burkholder et al. study

$$\ln(\sigma(\lambda, T)) = \sum_i A_i (\lambda - \bar{\lambda})^i \times \left[ 1 + (296 - T) \sum_i B_i (\lambda - \bar{\lambda})^i \right]$$

to parameterize the spectrum for wavelengths ≥260 nm and temperatures between 210 and 298 K using a combination of their cross section data and the data from Burkholder et al. The parameters are given below.

$\bar{\lambda} = 287.861$		
$i$	$A_i$	$B_i$
0	-47.4178	0.0003173
1	-0.1567273	$1.2323 \times 10^{-5}$
2	$-2.624376 \times 10^{-4}$	$2.68 \times 10^{-8}$
3	$-6.78412 \times 10^{-6}$	$-5.28 \times 10^{-9}$
4	$1.261478 \times 10^{-7}$	$6.99 \times 10^{-11}$

**Photolysis Quantum Yield and Product Studies:** The quantum yield for formation of CF<sub>2</sub>O and Br<sub>2</sub> in the photolysis of CF<sub>2</sub>Br<sub>2</sub> at 206, 248, and 302 nm in the presence of O<sub>2</sub> has been measured to be unity, independent of pressure, by Molina and Molina.<sup>7</sup> This is in contrast to an earlier report by Walton<sup>15</sup> that the quantum yield at 265 nm decreases from unity when the system pressure is raised to 50 Torr of CO<sub>2</sub>. Quantum yields for Br atom formation of  $\Phi(\text{Br}) = 1.96 \pm 0.27$ ,  $1.63 \pm 0.19$ , and  $1.01 \pm 0.15$ , in the photodissociation of CF<sub>2</sub>Br<sub>2</sub> at 193, 222, and 248 nm, respectively, were reported by Talukdar et al.<sup>13</sup> A quantum yield for CF<sub>2</sub> formation,  $\Phi(\text{CF}_2) = 1.15 \pm 0.30$ , in the 193 nm photolysis was reported by Talukdar et al.<sup>12</sup> The transient CF<sub>2</sub>Br radical was detected by molecular beam<sup>6</sup> and spectroscopic studies<sup>5,14</sup> during photolysis at 248 nm and confirm that the C-Br bond is broken.

## G26. $\text{CF}_2\text{ClBr}$ (Halon–1211, difluorochlorobromomethane)

[Back to Index](#)

(Recommendation: 15–10, Note: 15–10, Evaluated: 15–10)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{CF}_2\text{ClBr}$ , difluorochlorobromomethane (Halon–1211), has been measured at room temperature by Giolando et al.<sup>4</sup> (191–307 nm), Molina et al.<sup>5</sup> (190–330 nm), Orkin and Kasimovskaya<sup>6</sup> (190–304 nm), Gillotay and Simon<sup>3</sup> (170–302 nm), Burkholder et al.<sup>1</sup> (190–320 nm), and Papanastasiou et al.<sup>7</sup> (300–335 nm). The most recent study by Papanastasiou et al. reported absorption cross section data in the long wavelength region that were corrected for Rayleigh scattering, which is most important at the longest wavelengths. The agreement between the room temperature cross section data of Orkin and Kasimovskaya,<sup>6</sup> Gillotay and Simon,<sup>3</sup> and Burkholder et al.<sup>1</sup> is very good, to within 10%, over the range 190–240 nm and to within 3% at the spectrum maximum near 205 nm. The data from Gillotay and Simon<sup>3</sup> near the absorption maximum differs from the other observations by ~10%. Molina et al.<sup>5</sup> reported values in the range 190–240 nm that are lower by 10–20% than the other data. The few data points of Giolando et al.<sup>4</sup> agree well with the absorption spectra reported by Orkin and Kasimovskaya,<sup>6</sup> Gillotay and Simon,<sup>3</sup> and Burkholder et al.<sup>1</sup> The differences between the various data sets are greatest at the longer wavelengths. The recommended absorption cross sections in Table 4G-32 are the values of Gillotay and Simon<sup>3</sup> in the region 170–188 nm, the mean of the values reported by Molina et al.,<sup>5</sup> Gillotay and Simon,<sup>3</sup> Burkholder et al.,<sup>1</sup> and Orkin and Kasimovskaya<sup>6</sup> in the region 190–298 nm, the spectrum parameterization from Papanastasiou et al. for the region 300 to 350 nm (see below) (values  $\geq 336$  nm are an extrapolation beyond the range of the experimental data). The uncertainty factor for the room temperature spectrum is 1.15 ( $2\sigma$ ) for the range of data given in Table 4G-32, which encompasses the full range of the experimental data at wavelengths  $< 300$  nm as well as the data from Papanastasiou et al. at longer wavelengths.

The VUV absorption spectrum at room temperature was measured by Doucet et al.<sup>2</sup> (60–220 nm). A recommended Lyman- $\alpha$  cross section of  $7.75 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  was obtained from the two reported spectra by these authors. An uncertainty factor of 1.5 ( $2\sigma$ ) is assigned, primarily due to the fact that there is only a single study available.

The temperature dependence of the absorption spectrum has been measured by Gillotay and Simon<sup>3</sup> (210–296 K, 170–302 nm), Burkholder et al.<sup>1</sup> (210–296 K, 190–320 nm), and Papanastasiou et al. (210–296 K, 300–335 nm). The absorption cross sections increase near the peak, 204–206 nm, and decrease at wavelengths  $> 233$  nm and  $< 180$  nm with decreasing temperature. Gillotay and Simon<sup>3</sup> observed a systematic temperature dependence with an increase in the peak cross section by  $\sim 5 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  per 20 K decrease in temperature. Burkholder et al.<sup>1</sup> reported a less pronounced temperature dependence with the peak cross

section at 210 K being 15% less than reported Gillotay and Simon<sup>3</sup> (the room temperature cross sections from these two studies agree to within 4%). Different empirical parameterizations for the temperature dependence of the absorption cross section have been used. Gillotay and Simon<sup>3</sup> used a polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated cross sections for 210, 230, 250, 270, and 295 K. The  $A_n$  and  $B_n$  parameters, which are valid for the wavelength range 200–302 nm and temperature range 210–300 K, are given below.

$$\begin{array}{ll} A_0 = -134.80 & B_0 = 3.3070 \times 10^{-1} \\ A_1 = 1.7084 & B_1 = -5.0957 \times 10^{-3} \\ A_2 = -9.1540 \times 10^{-3} & B_2 = 2.9361 \times 10^{-5} \\ A_3 = 2.1644 \times 10^{-5} & B_3 = -7.6198 \times 10^{-8} \\ A_4 = -1.9863 \times 10^{-8} & B_4 = 7.6825 \times 10^{-11} \end{array}$$

Burkholder et al.<sup>1</sup> parameterized their data using the expression

$$\ln \sigma(\lambda, T) = (\sum A_i (\lambda - 259.8989)^i) (1 + (296 - T) \sum B_i (\lambda - 259.8989)^i)$$

and report the following  $A_i$  and  $B_i$  parameters valid for the wavelength range 220–260 nm and temperature range 210–296 K.

$$\begin{array}{ll} A_0 = -45.4087 & B_0 = 1.528905 \times 10^{-4} \\ A_1 = -1.304811 \times 10^{-1} & B_1 = 6.024833 \times 10^{-6} \\ A_2 = -6.995443 \times 10^{-4} & B_2 = 1.030995 \times 10^{-7} \\ A_3 = 6.159709 \times 10^{-6} & B_3 = -6.387931 \times 10^{-11} \\ A_4 = -9.384074 \times 10^{-9} & B_4 = -3.718503 \times 10^{-11} \end{array}$$

Burkholder et al.<sup>1</sup> also report a parameterization for cross sections extrapolated to 400 nm

$$\ln \sigma(\lambda, T) = (\sum A_i (\lambda - 292.2083)^i) (1 + (296 - T) \sum B_i (\lambda - 292.2083)^i)$$

with the following parameters.

$$\begin{array}{ll} A_0 = -50.15428 & B_0 = 3.778659 \times 10^{-4} \\ A_1 = -1.547025 \times 10^{-1} & B_1 = 6.338322 \times 10^{-6} \\ A_2 = -9.551083 \times 10^{-5} & B_2 = -1.294407 \times 10^{-8} \\ A_3 = 4.076334 \times 10^{-6} & B_3 = -2.430137 \times 10^{-10} \\ A_4 = -2.747685 \times 10^{-8} & B_4 = 2.234599 \times 10^{-12} \end{array}$$

Note: Errors in the Burkholder et al.<sup>1</sup> paper are corrected here.

The recommended spectrum parameterization for wavelengths >298 nm is taken from the Papanastasiou et al. study, which accounted for Rayleigh scattering that was significant for wavelengths >290 nm. They used the same empirical expression used in the Burkholder et al. study

$$\ln(\sigma(\lambda, T)) = \sum_i A_i (\lambda - \bar{\lambda})^i \times \left[ 1 + (296 - T) \sum_i B_i (\lambda - \bar{\lambda})^i \right]$$

to parameterize the spectrum for wavelengths  $\geq 260$  nm and temperatures between 210 and 298 K using a combination of their cross section data and the data from Burkholder et al. The parameters are given below.

$\bar{\lambda} = 280.376$		
$i$	$A_i$	$B_i$
0	-48.3578	0.0002989
1	-0.1547325	$8.5306 \times 10^{-6}$

## G27. CF<sub>3</sub>Br (Halon-1301, trifluorobromomethane)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

**Absorption Cross Sections:** The UV absorption spectrum of CF<sub>3</sub>Br, trifluorobromomethane (Halon-1301), has been measured at room temperature by Davidson<sup>2</sup> (207–255 nm), Roxlo and Mandl<sup>10</sup> (170–230 nm), Pence et al.<sup>9</sup> (180–400 nm), Molina et al.<sup>7</sup> (190–300 nm), Orkin and Kasimovskaya<sup>8</sup> (190–270 nm), Gillotay and Simon<sup>5</sup> (168–280 nm), and Burkholder et al.<sup>1</sup> (190–285 nm). The agreement between the room temperature data is in general good in the region between 190 and 230 nm, 10% or better. The exceptions are the data of Davidson<sup>2</sup> below 210 nm and the data set from Roxlo and Mandl.<sup>10</sup> Pence et al.<sup>9</sup> report a spectrum graphically and an absorption cross section at 193 nm that is significantly less than the rest of the data at 193 nm. For wavelengths >250 nm, Burkholder et al.<sup>1</sup> and Orkin and Kasimovskaya<sup>8</sup> report values greater by up to ~35% at 270 nm than reported by Molina et al.<sup>7</sup> and Gillotay and Simon.<sup>5</sup> The recommended absorption cross sections in Table 4G-33 are the values from Gillotay and Simon<sup>5</sup> in the region 168–188 nm, the mean of the values reported by Molina et al.,<sup>7</sup> Gillotay and Simon,<sup>5</sup> Burkholder et al.,<sup>1</sup> and Orkin and Kasimovskaya<sup>8</sup> in the region 190–270 nm, the mean of the values reported by Molina et al.,<sup>7</sup> Gillotay and Simon,<sup>5</sup> and Burkholder et al.<sup>1</sup> in the region 272–280 nm, and the values of Molina et al.<sup>7</sup> in the region 295–300 nm. The recommended uncertainty factors (2σ) are 1.15 (170–190 nm), 1.1 (190–230 nm), and 1.2 (230–280 nm) for the wavelength ranges in parenthesis. Due to the limited available experimental data, the uncertainty factor for wavelengths >280 nm is assigned a value of 2.

The VUV absorption spectrum has been measured by Doucet et al.<sup>4</sup> (120–206 nm), Doucet et al.<sup>3</sup> (60–128 nm), Suto and Lee<sup>11</sup> (106–152 nm), and Washida et al.<sup>13</sup> (116–130 nm). The Doucet et al. results near Lyman-α, 121.567 nm, are lower by ~40% than the Suto and Lee and Washida et al. results. The recommended Lyman-α cross section of  $2.5 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  is adopted from the SPARC lifetime report,<sup>6</sup> which is an average of the four studies, linearly interpolated to 121.567 nm. An uncertainty factor of 1.4 (2σ) that encompasses the available data is assigned.

The temperature dependence of the absorption spectrum has been measured by Gillotay and Simon<sup>5</sup> (168–280 nm) over the range 210–295 K and Burkholder et al.<sup>1</sup> (190–285 nm) over the range 210–296 K. The absorption cross sections increase between 174 and 216 nm and decrease at wavelengths >218 nm and <174 nm with decreasing temperature. Gillotay and Simon<sup>5</sup> observed a systematic temperature behavior with an increase of the peak cross section by  $\sim 0.6 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  per 20 K decrease in temperature. Burkholder et al.<sup>1</sup> reported a less pronounced temperature dependence with the peak cross section at 210 K being ~25% lower than reported by Gillotay and Simon<sup>5</sup> (the cross sections at room temperature are within 6%). Different parameterizations for the temperature dependence of the absorption cross section have been proposed. Gillotay and Simon<sup>5</sup> give the polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated values for T = 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, which are valid for the wavelength range 178–280 nm and temperature range 210–300 K are as follows.

A <sub>0</sub> = 62.563	B <sub>0</sub> = $-9.1755 \times 10^{-1}$
A <sub>1</sub> = -2.0068	B <sub>1</sub> = $1.8575 \times 10^{-2}$
A <sub>2</sub> = $1.6592 \times 10^{-2}$	B <sub>2</sub> = $-1.3857 \times 10^{-4}$
A <sub>3</sub> = $-5.6465 \times 10^{-5}$	B <sub>3</sub> = $4.5066 \times 10^{-7}$
A <sub>4</sub> = $6.7459 \times 10^{-8}$	B <sub>4</sub> = $-5.3803 \times 10^{-10}$

Burkholder et al.<sup>1</sup> parameterized their data using the expression

$$\ln \sigma(\lambda, T) = (\sum A_i (\lambda - 242.2466)^i) (1 + (296 - T) \sum B_i (\lambda - 242.266)^i)$$

and report the following A<sub>i</sub> and B<sub>i</sub> parameters valid for the wavelength range 214–285 nm and temperature range 210–296 K.

$$\begin{aligned}
A_0 &= -46.70542 & B_0 &= 1.694026 \times 10^{-4} \\
A_1 &= -1.55047 \times 10^{-1} & B_1 &= 8.723247 \times 10^{-6} \\
A_2 &= -1.020187 \times 10^{-3} & B_2 &= 5.953165 \times 10^{-9} \\
A_3 &= 2.246169 \times 10^{-5} & B_3 &= -3.872168 \times 10^{-9} \\
A_4 &= -1.300982 \times 10^{-7} & B_4 &= -1.803325 \times 10^{-11}
\end{aligned}$$

Note: In the Burkholder et al.<sup>1</sup> paper, the parameterization equation is written in terms of  $\log_{10} \sigma(\lambda, T)$  but the correct expression should be given in terms of  $\ln \sigma(\lambda, T)$ , as given here.

There is no apparent reason to prefer the spectrum temperature dependence reported by either Gillotay and Simon or Burkholder et al.

*Photolysis Quantum Yield and Product Studies:* Talukdar et al.<sup>12</sup> reported quantum yields for Br (Br( $^2P_{3/2}$  + Br\*( $^2P_{1/2}$ )) atom formation in the photodissociation of CF<sub>3</sub>Br at 193 and 222 nm to be  $1.12 \pm 0.16$  and  $0.92 \pm 0.15$ , respectively. A Br\*( $^2P_{1/2}$ ) atom fractional yield, Br\*( $^2P_{1/2}$ )/(Total Br), of  $0.56 \pm 0.05$  was reported by Pence et al.<sup>9</sup> for 193 nm photolysis.

## G28. CH<sub>2</sub>=CHBr (bromoethene, vinyl bromide)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of CH<sub>2</sub>=CHBr, bromoethene (vinyl bromide), has been measured at room temperature by Schander and Russell<sup>3</sup> (168–208 nm), Hoxha et al.<sup>1</sup> (62–248 nm), and Orkin et al.<sup>2</sup> (164–254 nm). The spectrum has a very strong absorption band with the maximum at 192 nm, characteristic of the CH<sub>2</sub>=CBr- group. The absorption cross sections reported in the Orkin et al.<sup>2</sup> study (reported in 0.5 nm increments) are recommended and given in Table 4G-34 for wavelengths ≥184 nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## G29. CHBr=CF<sub>2</sub> (1-bromo-2,2-difluoroethene)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CHBr=CF<sub>2</sub>, 1-bromo-2,2-difluoroethene, has been measured at room temperature over the wavelength range 164–266 nm by Orkin et al.<sup>1</sup> The spectrum has strong absorption bands between 164 and 190 nm, a weaker and less pronounced band between 190 and 210 nm (maximum 194 nm), and a still weaker band above 210 nm with the maximum near 220 nm. The absorption cross sections reported in the Orkin et al.<sup>1</sup> study (reported in 0.5 nm increments) are recommended and given in Table 4G-35 for wavelengths  $\geq 184$  nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4G-35. Recommended Absorption Cross Sections of CHBr=CF<sub>2</sub> at 295 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

## G30. CFBr=CF<sub>2</sub> (trifluorobromoethene)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CFBr=CF<sub>2</sub>, trifluorobromoethene, has been measured at room temperature over the wavelength range 164–274 nm by Orkin et al.<sup>1</sup> The spectrum has strong absorption bands between 164 and 188 nm, a weaker and less pronounced band between 188 and 213 nm (maximum 194.5 nm), and a still weaker band above 213 nm with the maximum near 229 nm. The absorption cross sections reported in the Orkin et al.<sup>1</sup> study (reported in 0.5 nm increments) are recommended and given in Table 4G-36 for wavelengths  $\geq 184$  nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4G-36. Recommended Absorption Cross Sections of CFBr=CF<sub>2</sub> at 295 K**

**G31. CH<sub>2</sub>=CBrCF<sub>3</sub> (2-bromo-3,3,3-trifluoro-1-propene)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CH<sub>2</sub>=CBrCF<sub>3</sub>, 2-bromo-3,3,3-trifluoro-1-propene, has been measured at room temperature over the wavelength range 164–254 nm by Orkin et al.<sup>1</sup> The spectrum has a very strong absorption band at wavelengths >174 nm with a maximum at 194 nm, similar to the CH<sub>2</sub>=CHBr spectrum and characteristic of a CH<sub>2</sub>=CBr- group. The recommended absorption cross sections in Table 4G-37 are taken from Orkin et al.<sup>1</sup> (reported in 0.5 nm increments).

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**G33. CF<sub>3</sub>CHClBr (Halon-2311, 1,1,1-trifluoro-2,2-chlorobromooethane)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CF<sub>3</sub>CHClBr, 1,1,1-trifluoro-2,2-chlorobromooethane (Halon-2311), has been measured at room temperature by Orkin and Kasimovskaya<sup>4</sup> (190–310 nm), Gillotay et al.<sup>2,3</sup> (170–290 nm), Bilde et al.<sup>1</sup> (200–310 nm), and Taketani et al.<sup>5</sup> (193.3 nm). The room temperature cross section values are in good agreement, to within 5–15%, at wavelengths <280 nm. In this region, Gillotay et al.<sup>2,3</sup> report the lowest cross section values and Orkin and Kasimovskaya<sup>4</sup> the greatest values. At wavelengths >280 nm, the data from Bilde et al. are greater than those of Orkin and Kasimovskaya<sup>4</sup> with the difference increasing with increasing wavelength, up to a factor of two at 310 nm. The recommended absorption cross sections in Table 4G-39 are the values from Gillotay et al.<sup>3</sup> in the region 170–188 nm, the mean of the values reported by Gillotay et al.<sup>3</sup> and Orkin and Kasimovskaya<sup>4</sup> in the region 190–198 nm, the mean of the values reported by the three groups in the region 200–290 nm, and the mean of the values reported by Orkin and Kasimovskaya<sup>4</sup> and Bilde et al.<sup>1</sup> in the region 292–310 nm.

The absorption spectrum temperature dependence has been measured by Gillotay et al.<sup>3</sup> (170–290 nm) over the range 210–295 K and Bilde et al.<sup>1</sup> (200–310 nm) over the range 223–298 K. Gillotay et al.<sup>3</sup> report an increase of the absorption cross sections near the maximum of the absorption band between 192 and 238 nm

with decreasing temperature and the opposite effect at wavelengths >238 nm and <192 nm. The increase at ~202 nm is  $\sim 2.4 \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$  per 20 K decrease in temperature, i.e., an increase of ~10% between 295 and 210 K. Bilde et al.<sup>1</sup> observed a less pronounced temperature behavior in the absorption band and a decrease of the absorption cross sections with decreasing temperature at wavelengths above 214 nm.

Gillotay et al.<sup>3</sup> parameterized the cross sections and the temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated values for 210, 230, 250, 270, and 295 K. The  $A_n$  and  $B_n$  parameters, which are valid for the wavelength range 190–290 nm and temperature range 210–300 K, are given below and are recommended.

$A_0 = -127.157358$	$B_0 = -7.959828 \times 10^{-2}$
$A_1 = 1.635435$	$B_1 = 1.978026 \times 10^{-3}$
$A_2 = -9.002683 \times 10^{-3}$	$B_2 = -1.627866 \times 10^{-5}$
$A_3 = 2.190678 \times 10^{-5}$	$B_3 = 5.480744 \times 10^{-8}$
$A_4 = -2.062651 \times 10^{-8}$	$B_4 = -6.480935 \times 10^{-11}$

*Photolysis Quantum Yield and Product Studies:* Taketani et al.<sup>5</sup> reported the total yield of Cl atoms to be  $0.28 \pm 0.02$  in the photodissociation of  $\text{CF}_3\text{CHClBr}$  at 193.3 nm. Assuming a unit quantum yield for photodissociation this implies that the rupture of the C-Br bond should be dominant photodissociation channel.

### G35. $\text{CF}_2\text{BrCF}_2\text{Br}$ (Halon–2402, 1,1,2,2-tetrafluoro-1,2-dibromoethane)

[Back to Index](#)

(1)

(2)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The absorption cross sections of  $\text{CF}_2\text{BrCF}_2\text{Br}$ , 1,1,2,2-tetrafluoro-1,2-dibromoethane (Halon–2402), has been measured at room temperature by Molina et al.<sup>3</sup> (195–320 nm), Orkin and Kasimovskaya<sup>4</sup> (190–300 nm), Gillotay et al.<sup>2</sup> (170–280 nm), Burkholder et al.<sup>1</sup> (190–320 nm), and Papanastasiou et al.<sup>5</sup> (300–320 nm). The most recent study by Papanastasiou et al. reported absorption cross

section data in the long wavelength region that were corrected for Rayleigh scattering, which is most important at the longest wavelengths. The room temperature absorption cross sections are in good agreement in the region 180–290 nm, generally to within 10%. The agreement at the absorption maximum near 200 nm is to within 5% and in the long wavelength tail out to 310 nm it is to within 15%. The recommended absorption cross sections in Table 4G-41 are the values from Gillotay et al.<sup>2</sup> in the region 170–186 nm, the mean of the values reported by Molina et al.,<sup>3</sup> Gillotay et al.,<sup>2</sup> Burkholder et al.,<sup>1</sup> and Orkin and Kasimovskaya<sup>4</sup> in the region 196–264 nm, and the parameterization from Papanastasiou et al.<sup>5</sup> in the region >264 nm (see below). In the region 186 and 196 nm, a smoothed absorption spectrum was used to estimate values at 188, 190, 192, and 194 nm. An uncertainty factor of 1.15 (2 $\sigma$ ) is recommended for the room temperature spectrum over the wavelength range where experimental data are available.

There are no VUV spectrum measurements available for Halon-2402. The Lyman- $\alpha$ , 121.567 nm, cross section is expected to be greater than that for CF<sub>3</sub>Br (Halon-1301) and less than that for CF<sub>2</sub>Br<sub>2</sub> (Halon-1202). A Lyman- $\alpha$  cross section of  $5 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup> is estimated and an uncertainty factor of 2 assigned.

The temperature dependence of the absorption spectrum has been measured by Gillotay et al.<sup>2</sup> (170–280 nm) over the range 210–295 K, Burkholder et al.<sup>1</sup> (190–320 nm) over the range 210–296 K, and Papanastasiou et al. over the range 250–296 K. The Gillotay et al. and Burkholder et al. studies do not agree on the spectrum temperature dependence with the Burkholder et al. spectrum having a systematically greater temperature dependence at wavelengths <230 nm and weaker dependence at longer wavelengths. Gillotay et al. report a decrease in the absorption maximum at 200 nm of  $\sim 1.0 \times 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup> per 20 K temperature decrease, i.e., a decrease of ~4% between 295 and 210 K. Burkholder et al.<sup>1</sup> report an increase in the peak absorption cross section of ~20% with decreasing temperature over the full temperature range studied. Gillotay et al.<sup>2</sup> parameterized the cross section temperature dependence using an empirical polynomial expansion

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T - 273) \times \sum B_n \lambda^n$$

and report calculated values for 210, 230, 250, 270, and 295 K. The A<sub>n</sub> and B<sub>n</sub> parameters, which are valid for the wavelength range 190–290 nm and temperature range 210–300 K are given below.

A <sub>0</sub> = 34.026000	B <sub>0</sub> = $4.010664 \times 10^{-1}$
A <sub>1</sub> = -1.152616	B <sub>1</sub> = $-8.358968 \times 10^{-3}$
A <sub>2</sub> = $8.959798 \times 10^{-3}$	B <sub>2</sub> = $6.415741 \times 10^{-5}$
A <sub>3</sub> = $-2.9089 \times 10^{-5}$	B <sub>3</sub> = $-2.157554 \times 10^{-7}$
A <sub>4</sub> = $3.307212 \times 10^{-8}$	B <sub>4</sub> = $2.691871 \times 10^{-10}$

Burkholder et al.<sup>1</sup> parameterized the temperature dependence using the empirical expression

$$\ln \sigma(\lambda, T) = (\sum A_i (\lambda - 242.4015)^i) (1 + (296 - T) \sum B_i (\lambda - 242.4015)^i)$$

and report the following A<sub>i</sub> and B<sub>i</sub> parameters for the wavelength range 190–320 nm and temperature range 210–296 K.

A <sub>0</sub> = -43.69218	B <sub>0</sub> = $3.301341 \times 10^{-5}$
A <sub>1</sub> = $-1.124704 \times 10^{-1}$	B <sub>1</sub> = $4.695917 \times 10^{-6}$
A <sub>2</sub> = $-1.213301 \times 10^{-3}$	B <sub>2</sub> = $6.128629 \times 10^{-8}$
A <sub>3</sub> = $5.275007 \times 10^{-6}$	B <sub>3</sub> = $-5.443107 \times 10^{-10}$
A <sub>4</sub> = $6.936195 \times 10^{-8}$	B <sub>4</sub> = $-1.035596 \times 10^{-11}$

Note: In the original Burkholder et al.<sup>1</sup> paper, the parameterization equation is written in terms of  $\log_{10} \sigma(\lambda, T)$  but the correct expression should be given in terms of  $\ln \sigma(\lambda, T)$ , as given here.

The recommended spectrum parameterization for wavelengths >264 nm is taken from the Papanastasiou et al. study, which accounted for Rayleigh scattering that was significant for wavelengths >290 nm. They used the empirical expression used in the Burkholder et al. study

$$\ln(\sigma(\lambda, T)) = \sum_i A_i (\lambda - \bar{\lambda})^i \times \left[ 1 + (296 - T) \sum_i B_i (\lambda - \bar{\lambda})^i \right]$$

to parameterize the spectrum for wavelengths ≥260 nm and temperatures between 210 and 298 K using a combination of their cross section data and data from Burkholder et al. The parameters are given below.

$\bar{\lambda} = 274.64$			
$i$		$A_i$	$B_i$
0		-48.3611	0.0001877
1		-0.1595	$7.252 \times 10^{-6}$
2		$-1.026 \times 10^{-4}$	$2.917 \times 10^{-7}$
3		$1.334 \times 10^{-5}$	$-1.725 \times 10^{-9}$
4		$1.458 \times 10^{-7}$	$-2.675 \times 10^{-11}$

For wavelengths  $< 266$  nm, there is no apparent reason to prefer the spectrum temperature dependence reported by either Gillotay et al. or Burkholder et al.

*Photolysis Quantum Yield and Product Studies:* Zou et al.<sup>6</sup> report quantum yields for Br atom formation in the photodissociation of CF<sub>2</sub>BrCF<sub>2</sub>Br at 193, 233, and 266 nm to be  $1.9 \pm 0.1$ ,  $1.9 \pm 0.1$ , and  $1.4 \pm 0.1$ , respectively. These results indicate bond breaking of both C–Br bonds for photolysis at 193 and 233 nm and at an appreciable fraction at 266 nm.

### G36. $\text{CF}_3\text{CF}_2\text{Br}$ (Halon-2501, pentafluorobromoethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{CF}_3\text{CF}_2\text{Br}$ , pentafluorobromoethane (Halon-2501), has been measured at room temperature by Molina et al.<sup>2</sup> (190–300 nm), Zhang et al.<sup>4</sup> (200–250 nm), and Pence et al.<sup>3</sup> (180–400 nm, 193 nm). The absorption cross sections from Zhang et al.,<sup>4</sup> reported graphically, are ~30% greater than the results from Molina et al.<sup>2</sup> Pence et al.<sup>3</sup> report a spectrum graphically over the range 180–400 nm and a 193 nm cross section that is ~40% less than reported by Molina et al.<sup>2</sup> The recommended absorption cross sections in Table 4G-42 are taken from Molina et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* Ebenstein et al.<sup>1</sup> used broadband flash photolysis of  $\text{CF}_3\text{CF}_2\text{Br}$  and reported a  $\text{Br}^*(^2\text{P}_{1/2})$  fractional yield,  $\text{Br}^*(^2\text{P}_{1/2})/\text{(Total Br)}$ , of  $0.48 \pm 0.02$ . A  $\text{Br}^*(^2\text{P}_{1/2})$  fractional yield of  $0.16 \pm 0.08$  was reported by Pence et al.<sup>3</sup> for 193 nm photolysis.

**G37. CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>Br (1-bromopropane, n-propyl bromide)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>Br, 1-bromopropane (n-propyl bromide), has been measured at room temperature by Kozlov et al.<sup>1</sup> (164–270 nm). The spectrum has an absorption band above 180 nm with maxima at ~201 nm and structured features at wavelengths <180 nm similar to those in the CH<sub>3</sub>Br spectrum, i.e., characteristic of the C-Br band absorptions in bromoalkanes. The recommended absorption cross sections in Table 4G-43 are taken from Kozlov et al.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**G39. CH<sub>3</sub>C(O)CH<sub>2</sub>Br (bromoacetone)**[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of  $\text{CH}_3\text{C(O)CH}_2\text{Br}$ , bromoacetone, has been measured by Burkholder et al.<sup>1</sup> (210–370 nm) over the temperature range 238–296 K using a diode array spectrometer (0.6 nm resolution). The spectrum has overlapping absorption bands with a maximum at 299 nm ( $\sigma = 1.15 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  at room temperature) and increasing absorption cross sections below 255 nm to a second stronger band peaking below 210 nm. The recommended absorption cross sections in Table 4G-44 are taken from Burkholder et al.<sup>1</sup> A slight, but not systematic, decrease of the absorption cross sections with decreasing temperature was observed around the absorption minimum at 255 nm and in the long wavelength wings of both absorption bands.

*Photolysis Quantum Yield and Product Studies:* The photodissociation quantum yield was measured by Burkholder et al.<sup>1</sup> to be  $1.6 \pm 0.25$  at 308 nm and  $1.0 \pm 0.15$  at 351 nm. At both wavelengths, the yields of CO and  $\text{CO}_2$  were unity and  $\sim 0.5$ , respectively, whereas the yield of  $\text{HC(O)OH}$  was measured to be 0.15 and that of HBr to be  $\sim 0.15$ .

## SECTION 4H. IO<sub>x</sub> PHOTOCHEMISTRY

### H1. I<sub>2</sub> (molecular iodine)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV/vis absorption spectrum of I<sub>2</sub>, molecular iodine, between 180 and 750 nm consists of several overlapping electronic transitions. The spectrum has a strong absorption band below 210 nm that peaks at ~181 nm and contains some diffuse band structure. Between 210 and 380 nm the spectrum is continuous with decreasing absorption cross sections toward longer wavelength and a minimum cross section of  $\sim 1 \times 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup> at 380 nm. The visible region of the spectrum shows a strong broad band between 400 and 650 nm that is continuous below 500 nm but shows pronounced rovibrational structure between 500 and 630 nm. The structure is due to the transition from the X<sup>1</sup>Σ ground state to the bound B<sup>3</sup>Π upper state. There is also a weaker underlying continuum in the structured region with a maximum near 533 nm that is due to a transition to a <sup>1</sup>Π repulsive state. At wavelengths >650 nm there is evidence for another weak absorption band. There have been numerous studies of the I<sub>2</sub> absorption spectrum as summarized in Table 4H-1.

**Table 4H-1. Summary of I<sub>2</sub> Absorption Cross Sections Studies**

Study	Year	Temperature (K)	Wavelength (nm)	$10^{20} \sigma(500 \text{ nm}) (\text{cm}^2)$

Tellinghuisen <sup>14</sup>	2011	273–337	520–640	—

Note:

Uncertainties as reported

\* Cross section values at 488 nm are in the range  $(176\text{--}113) \times 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup> over the temperature range 423–1323 K

The cross section data sets from Tellinghuisen,<sup>13</sup> Saiz-Lopez et al.,<sup>9</sup> and Spietz et al.<sup>10,11</sup> are the primary focus of this evaluation. Tellinghuisen<sup>13</sup> reported room temperature cross sections obtained with a continuum light source at moderate resolution (~2.5 nm). Saiz-Lopez et al.<sup>9</sup> used a Fourier transform spectrometer to record spectra at a resolution of 4 cm<sup>-1</sup> (0.1 nm at 500 nm). Spietz<sup>10,11</sup> used a grating/CCD spectrometer with a resolution of 0.25 nm. The reported spectra show the largest differences in the structured and long wavelength regions of the spectrum. A direct comparison of cross section data in the structured region is, however, difficult due to the differences in measurement resolution. Saiz-Lopez et al.<sup>9</sup> examined the cross section dependence on absolute I<sub>2</sub> concentration and bath gas pressure. Their final cross section data were obtained at high bath gas pressure and high resolution. The cross section data sets agree in the structured region to within ~15% when averages over 5 nm intervals are compared. There are significant discrepancies between the Tellinghuisen<sup>13</sup> and Saiz-Lopez et al.<sup>9</sup> spectra at wavelengths >~600 nm with differences increasing from 35% at 600 nm to factors of ~2 and ~20 at 710 and 740 nm, respectively. The cross sections reported by Bauer et al.<sup>1</sup> at 436 and 500 nm,  $(1.41 \pm 0.05) \times 10^{-18}$  and  $(2.25 \pm 0.09) \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup>, respectively, are in agreement with the Saiz-Lopez et al.<sup>9</sup> values. Tellinghuisen<sup>14</sup> used his I<sub>2</sub> spectrum measured at 0.1 nm resolution to determine the B-X transition moment.

The absorption cross sections listed in Table 4H-2 are averages over 5 nm intervals (+2 to -2 nm of the center wavelength) of the data reported by Saiz-Lopez et al.<sup>9</sup> The average values in Table 4H-2 removes the vibrational band structure in the spectrum and smoothes the data elsewhere. The data in Table 4H-2 are appropriate for atmospheric photolysis rate calculations. Higher resolution cross section data should be obtained from the original studies. Table 4H-3 lists the absorption cross sections at the maxima and minima in the banded region reported by Saiz-Lopez et al.<sup>9</sup>

*Photolysis Quantum Yield and Product Studies:* Photodissociation quantum yields for I<sub>2</sub> in the structured region of the spectrum were measured by Brewer and Tellinghuisen<sup>2</sup> using atomic fluorescence under conditions of steady-state irradiation of I<sub>2</sub> at 12 wavelengths in the region 501–624 nm. The quantum yields were determined relative to the purely dissociative continuum at 492 nm, where a unity quantum yield is assumed. The quantum yields were found to be wavelength dependent with values ranging from 0.9 to 0.33.

## H2. IO (iodine monoxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The A  $^2\Pi_{3/2} \leftarrow X ^2\Pi_{3/2}$  electronic transition for IO, iodine monoxide, yields a UV/vis absorption spectrum between 338 and 488 nm. The A –X band consists of a continuous absorption band with a maximum near 400 nm with a broad progression of vibrational bands superimposed on the continuum at wavelengths >400 nm. The pronounced vibrational band structure has been assigned to progressions in v', 7-0←-0 and 3-1←-1. Of particular interest (e.g. for the study of the reaction kinetics of IO) is the peak absorption cross section of the strongest vibrational band (4,0) at 427.2 nm. A summary of the available studies (which utilized photolysis of N<sub>2</sub>O/I<sub>2</sub>, N<sub>2</sub>O/CF<sub>3</sub>I, and O<sub>3</sub>/I<sub>2</sub> mixtures to produce IO) and the corresponding (4,0) peak cross sections at room temperature is given in Table 4H-4.

**Table 4H-4. Summary of IO Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength Range (nm)	Resolution (nm)	$\sigma(427.2 \text{ nm}) 10^{-17} \text{ cm}^2$

\* Average value between 203 and 373 K (see text)

The shape of the 298 K spectra reported by Laszlo et al., Harwood et al., and Bloss et al. are similar but with notable differences in the magnitude of the vibrational features due to the dependence on the resolution of the measurement. The absorption cross sections reported by Harwood et al. with a resolution of 0.44 nm and scaled to 0.83 of the value obtained for the (4,0) peak cross section at higher resolution, 0.14 nm, are generally (with exceptions in the region 350–415 nm) higher than those reported by Lazlo et al. (0.3 nm resolution) and Bloss et al. (1.13 nm resolution). The Bloss et al. cross section data are the lowest throughout the spectral region 340–465 nm. The Bloss et al. cross section data are lower than the values reported by Harwood et al. by a factor of ~1.5 in the continuous region of the spectrum and at the peaks of the vibrational bands and up to factor of 5 at the minima between the vibrational bands. Bloss et al. attributed the differences in the spectra to an underlying absorption due to the absorbing species I<sub>2</sub>O<sub>2</sub> that is considered to be a product of the IO self-reaction. The absorption spectrum of I<sub>2</sub>O<sub>2</sub> is currently not known.

The absorption spectrum reported by Laszlo et al. is higher by a factor of ~1.2–1.5 in the wavelength region 350–370 nm and at the maxima in the 395–405 nm region than the values reported by Harwood et al. However, the spectra are similar in the region of the (6,0) to (4,0) maxima. The absorption cross section measured by Atkinson et al. at high resolution (0.0013 nm) for the (2,0) peak is higher by a factor of ~5 than that reported by Harwood et al., whereas the cross sections reported by Atkinson et al. and Harwood et al. for the (1,0) maximum are nearly the same.

The recommended cross sections in Table 4H-5 were obtained as follows: (1) the spectra of Harwood et al. and Laszlo et al. were degraded to the resolution of the spectrum of Bloss et al. (1.13 nm), (2) the degraded spectra of Harwood et al. were normalized to the (4,0) peak value of Bloss et al., (3) the mean of the degraded and normalized spectra of Harwood et al. and Laszlo et al. and that of Bloss et al. were calculated and averaged over 1 nm intervals. The studies of Dillon et al.,<sup>4</sup> Gómez Martin et al.,<sup>5</sup> and Spietz et al.<sup>11</sup> are noted but not considered in the present evaluation.

The temperature dependence of the absorption cross section of the (4,0) peak has been studied by Sander (250–373 K), Harwood et al. (203–373 K), and Bloss et al. (220–325 K). The results from these studies are significantly different. Sander report a significant increase in  $\sigma(427 \text{ nm})$  from a value of  $(2.1 \pm 0.1) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 373 K to  $(5.3 \pm 0.5) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 250 K. Bloss et al. report a smaller increase in the absorption cross sections with the ratio  $\sigma(T)/\sigma(295 \text{ K})$  being 0.85 and 1.23 at 325 K and 220 K, respectively. Harwood et al. used several pulsed laser photolysis sources of IO (N<sub>2</sub>O/CF<sub>3</sub>I, O<sub>3</sub>/I<sub>2</sub>, and N<sub>2</sub>O/I<sub>2</sub>) in their experiments and reported absorption cross sections between  $(3.1 \pm 0.4) \times 10^{-17}$  and  $(3.9 \pm 0.1) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  independent of temperature (203–373 K) and report an average value of  $(3.6 \pm 0.5) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ .

**Photolysis Quantum Yield and Product Studies:** The quantum yield for O(<sup>3</sup>P) formation following photolysis of IO at 355 nm was measured relative to NO<sub>2</sub> photolysis at the same wavelength to be 0.91 (<sup>+0.19</sup><sub>-0.26</sub>) by Ingham et al.<sup>7</sup> The lifetime of the A <sup>2</sup>P<sub>3/2</sub> was measured to be < 20 ns by Turnipseed et al.,<sup>13</sup> which indicates that electronic collisional quenching does not compete with the dissociation into O(<sup>3</sup>P) + I. This is consistent with the results of Ingham et al.

**Table 4H-5. Recommended Absorption Cross Sections of IO at 298 K**

### H3. OIO (iodine dioxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* A qualitative absorption spectrum of OIO, iodine dioxide, was first reported by Himmelmann et al.<sup>7</sup> at 298 K over the wavelength range 476–667 nm. The absorption spectrum is highly structured due to transitions in the  $\text{A}({}^2\text{A}_2)$  ( $i,j,k$ )  $\leftarrow \text{X}({}^2\text{B}_1)$  (0,0,0) band with vibrational progressions in the upper state of the symmetric I-O stretch ( $i = 0-9$ ) and O-I-O bend ( $j = 0, 1, 2$ ). Absorption cross sections have been measured at room temperature by Cox et al.<sup>3</sup> (400–600 nm) and Bloss et al.<sup>2</sup> (514–573 nm) at a resolution of 1.13 nm, by Spietz et al.<sup>10</sup> (392–660 nm) and Gómez Martín et al.<sup>6</sup> at a resolution of 1.3 nm who report a cross section of  $(1.3 \pm 0.3) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 549.1 nm, and at high resolution (<0.006 nm) using cavity ring-down spectroscopy by Ashworth et al.<sup>1</sup> and Joseph et al.<sup>9</sup> (558–578 nm). Joseph et al.<sup>9</sup> report a cross section of  $(1.5 \pm 0.18) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 567.93 nm.

The peak cross sections at 562 and 568 nm obtained at high resolution are higher by a factor ~1.7 than those reported for a resolution of 1.13 nm. The recommended cross sections listed in Table 4H-6 were obtained by averaging the data reported by Bloss et al.<sup>2</sup> over 1 nm intervals (reported at intervals of 0.22 nm). The estimated uncertainty in the absolute absorption cross sections is a factor of 3.

*Photolysis Quantum Yield and Product Studies:* Ingham et al.<sup>8</sup> studied the photodissociation of OIO at 532 nm. O(<sup>3</sup>P) atom formation was not detected and an upper limit for the O atom quantum yield of <0.012 was reported (based on an OIO absorption cross section of  $2.4 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 532 nm). Subsequently, Ashworth et al.<sup>1</sup> inferred that OIO predissociates to  $\text{I} + \text{O}_2$  via the upper <sup>2</sup>B<sub>2</sub> state. Ingham et al.<sup>8</sup> detected I(<sup>2</sup>P<sub>J</sub>) atoms at high photolysis laser fluence, presumably in a sequential two-photon process, and an upper limit for the I atom quantum yield of < 0.15 was reported. Joseph et al.<sup>9</sup> report the photolysis quantum yield of OIO at 562 nm to be <0.10. Tucceri et al.<sup>11</sup> used pulsed laser photolysis combined with transient absorption spectroscopy/resonance fluorescence detection techniques and reported I atom quantum yields of <0.05 in the wavelength range 560–580 nm and <0.24 at 532 nm. A study by Gómez Martín et al.<sup>5</sup> contradicts the results from Joseph et al.,<sup>9</sup> Ingham et al.,<sup>8</sup> and Tucceri et al.<sup>11</sup> Gómez Martín et al.<sup>5</sup> used a tunable pulsed laser photolysis source combined with cavity ring-down spectroscopy detection of OIO and atomic resonance fluorescence detection of I atoms. They report an I atom quantum yield of  $(1.07 \pm 0.15)$  over the wavelength range 480–650 nm. In an additional study from the same group, Gómez Martín et al.<sup>4</sup> report the IO quantum yield to be unity at wavelengths <480 nm. No quantum yield recommendation is given.

**H4. HI (hydrogen iodide)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of HI, hydrogen iodide, at wavelengths >180 nm has a continuous absorption band with a maximum near 222 nm. At wavelengths <180 nm the spectrum shows strong diffuse band structure. The available studies are summarized in Table 4H-7. For wavelengths >180 nm, there is good agreement between the room temperature absorption cross sections reported by Campuzano-Jost and Crowley,<sup>3</sup> Ogilvie,<sup>9</sup> and Huebert and Martin.<sup>6</sup> The data reported by Huebert and Martin<sup>6</sup> and Campuzano-Jost and Crowley<sup>3</sup> are nearly identical around the absorption maximum and out to ~275 nm. The cross sections reported by Ogilvie<sup>9</sup> are slightly greater. At wavelengths >280 nm, the absorption spectra from these three studies diverge somewhat with the cross sections reported by Huebert and Martin<sup>6</sup> being greater and those of Ogilvie<sup>9</sup> being smaller than the cross sections reported by Campuzano-Jost and Crowley.<sup>3</sup> The recommended cross sections listed in Table 4H-8 are average values over 1 nm intervals of the high resolution (0.08 nm) data from Campuzano-Jost and Crowley.<sup>3</sup>

**Table 4H-7. Summary of HI Absorption Cross Sections Studies**

Study	Year	Temperature (K)	Wavelength (nm)	$10^{20} \sigma(222 \text{ nm}) (\text{cm}^2)$

Note:

Campuzano-Jost and Crowley,<sup>3</sup> averaged (see text).

*Photolysis Quantum Yield and Product Studies:* Martin and Willard<sup>8</sup> measured the quantum yield for H and I atoms in the photolysis of HI at 184.9 and 253.7 nm to be near unity. A quantum yield for the loss of HI of unity is recommended for wavelengths >180 nm. Brewer et al.<sup>1</sup> reported the relative quantum yield for the formation of I\*(<sup>2</sup>P<sub>1/2</sub>) to be 0.47 ± 0.03 at 248 nm. Using broadband flash photolysis, Donohue and Wiesenfeld<sup>4</sup> obtained an I\*(<sup>2</sup>P<sub>1/2</sub>) yield of 0.10 ± 0.05. Langford et al.<sup>7</sup> measured the branching ratio I\*(<sup>2</sup>P<sub>1/2</sub>)/I(<sup>2</sup>P<sub>3/2</sub>) in a detailed study at 24 different wavelengths in the range 200–303 nm. They reported a wavelength dependence of the ratio with a value of 0.2 near 208 nm, a maximum value of 1.7 near 252 nm, and a value of 0.1 at 303 nm. These authors review several similar earlier studies and should be consulted for more detailed information.

## H5. HOI (hypoiiodous acid)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of HOI, hypoiiodous acid, has been measured at room temperature by Bauer et al.<sup>1</sup> (280–500 nm) and Rowley et al.<sup>2</sup> (280–450 nm). In these studies HOI was produced by reacting OH, which was generated by pulsed laser photolysis, with I<sub>2</sub>. Absorption cross sections were determined assuming iodine mass balance and the measured loss of I<sub>2</sub>. Two absorption bands of comparable intensity were observed, one between 280 and ~375 nm with a maximum near 340 nm and the other between ~375 and 500 nm with a maximum near 408 nm. The spectra of Bauer et al.<sup>1</sup> and Rowley et al.<sup>2</sup> are in reasonable agreement with slight differences in the wavelength of the absorption maxima, 2–3 nm, and absolute cross sections, less than ~15% difference. The recommended cross sections listed in Table 4H-9 are the mean of the values reported by Rowley et al.<sup>2</sup> and Bauer et al.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* The OH quantum yield in the photolysis of HOI at 355 nm was measured by Bauer et al. to be close to unity.

**Table 4H-9. Recommended Absorption Cross Sections of HOI at 298 K**

**H6. ICl (iodine chloride)**[Back to Index](#)

ICl + hν	→ I( <sup>3</sup> P <sub>3/2</sub> ) + Cl( <sup>3</sup> P <sub>3/2</sub> )	210 kJ mol <sup>-1</sup>	569 nm	(1)
	→ I( <sup>3</sup> P <sub>3/2</sub> ) + Cl*( <sup>3</sup> P <sub>1/2</sub> )	221 kJ mol <sup>-1</sup>	542 nm	(2)
	→ I*( <sup>3</sup> P <sub>1/2</sub> ) + Cl( <sup>3</sup> P <sub>3/2</sub> )	301 kJ mol <sup>-1</sup>	397 nm	(3)
	→ I*( <sup>3</sup> P <sub>1/2</sub> ) + Cl*( <sup>3</sup> P <sub>1/2</sub> )	312 kJ mol <sup>-1</sup>	384 nm	(4)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of ICl, iodine chloride, has been measured at room temperature by Gibson and Ramsperger<sup>4</sup> (380–570 nm), Seery and Britton<sup>9</sup> (220–600 nm), Binder<sup>1</sup> (216.5–310 nm), and Jenkin et al.<sup>5</sup> (210–690 nm). Spectra measured at elevated temperatures have been reported by Binder<sup>1</sup> (293, 387, 489, and 685 K). The spectrum shows two absorption bands of nearly equal peak height, one between 220 and 350 nm with the maximum at ~244 nm and one between 350 and 600 nm with the maximum near 470 nm. The latter band is asymmetric due to the overlap of the B <sup>3</sup>Π<sub>0+</sub> ← X <sup>1</sup>Σ<sub>0+</sub>, <sup>1</sup>Π ← X <sup>1</sup>Σ<sub>0+</sub>, and A <sup>3</sup>Π<sub>i</sub> ← X <sup>1</sup>Σ<sub>0+</sub> transitions, as discussed by Seery and Britton<sup>9</sup> and Mashnin et al.<sup>7</sup> The experimental data of Seery and Britton<sup>9</sup> and Jenkin et al.<sup>5</sup> are in excellent agreement in the region of the visible absorption band but are appreciably higher (by ~35% at the maximum) than the earlier data from Gibson and Ramsperger.<sup>4</sup> The cross section at the 242 nm maximum reported by Jenkin et al.<sup>5</sup> is greater by ~14% than those observed by Gibson and Ramsperger<sup>4</sup> and Seery and Britton.<sup>9</sup> The larger absorption cross sections reported by Seery and Britton<sup>9</sup> over the wavelength range 290–360 nm are most likely due to Cl<sub>2</sub> impurities as argued by Jenkin et al.,<sup>5</sup> who subtracted Cl<sub>2</sub> contributions in their spectral analysis. Jenkin et al.<sup>5</sup> report their absorption spectrum in graphical form along with cross section values of  $5.00 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> and  $4.20 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> at 244 nm and 467 nm, respectively. The recommended cross sections in Table 4H-10 use these values combined with the absorption cross sections read from a figure given in Jenkin et al.<sup>5</sup>

Binder<sup>1</sup> report a decrease in the 244 nm peak absorption cross section with increasing temperature from  $4.40 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> at 293 K to  $3.53 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> at 685 K.

*Photolysis Quantum Yield and Product Studies:* The ratio of the Cl atom spin-state quantum yields,  $\Phi(\text{Cl}^*)/(\Phi(\text{Cl}^*) + \Phi(\text{Cl}))$ , has been reported by several groups. Mashnin et al.<sup>7</sup> showed that for wavelengths in the range 437–532 nm the ratio varied between  $0.41 \pm 0.02$  and  $0.79 \pm 0.02$ . The ratio has been reported by Ni and Flynn<sup>8</sup> to be  $0.17 \pm 0.04$  at 237 nm,  $0.67 \pm 0.05$  at 248 nm by Chichinin,<sup>2</sup> and  $0.55 \pm 0.05$  at 530 nm by Chichinin et al.<sup>3</sup> Tonokura et al.<sup>10</sup> reported  $\Phi(\text{I} + \text{Cl})$ ,  $\Phi(\text{I} + \text{Cl}^*)$ , and  $\Phi(\text{I}^* + \text{Cl})$  to be 0.2, 0.4 and 0.4, respectively, for the wavelength range 235–248 nm. The ratio of I\* to I,  $I^*/I$ , has been reported by Tonokura et al.<sup>10</sup> to be  $0.71 \pm 0.27$  and Jung et al.<sup>6</sup> to be 0.43 at 304 nm.

## H7. IBr (iodine bromide)

[Back to Index](#)

IBr + hν	→ I( <sup>3</sup> P <sub>3/2</sub> ) + Br( <sup>3</sup> P <sub>3/2</sub> )	178 kJ mol <sup>-1</sup>	673 nm	(1)
	→ I( <sup>3</sup> P <sub>3/2</sub> ) + Br*( <sup>3</sup> P <sub>1/2</sub> )	222 kJ mol <sup>-1</sup>	539 nm	(2)
	→ I*( <sup>3</sup> P <sub>1/2</sub> ) + Br( <sup>3</sup> P <sub>3/2</sub> )	269 kJ mol <sup>-1</sup>	446 nm	(3)
	→ I*( <sup>3</sup> P <sub>1/2</sub> ) + Br*( <sup>3</sup> P <sub>1/2</sub> )	312 kJ mol <sup>-1</sup>	383 nm	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of IBr, iodine bromide, has been measured at room temperature by Seery and Britton<sup>4</sup> over the wavelength range 220–600 nm. The spectrum consists of two absorption bands, a weak band between 220 and 350 nm with the maximum at ~270 nm and a stronger band between 350 and 600 nm with the maximum at ~500 nm. The recommended absorption cross sections in Table 4H-11 are taken from Seery and Britton.<sup>4</sup>

*Photolysis Quantum Yield and Product Studies:* Absolute quantum yields for Br\* formation, Φ(Br\*), were measured by Haugen et al.<sup>1</sup> over the wavelength range 450–530 nm. Φ(Br\*) increases from a value of 0.28 at 450 nm to a maximum of 0.73 near 500 nm. Peterson and Smith<sup>3</sup> reported the ratio of the Br atom spin-state quantum yields, Φ(Br\*)/(Φ(Br\*) + Φ(Br)), to vary from ~0.3 at 444 nm to a maximum of unity near 520 nm followed by a decline to ~0.1 at 670 nm. Wrede et al.<sup>5</sup> reported a similar trend over the wavelength range 440–544 nm. Kim et al.<sup>2</sup> measured the relative quantum yields for the photolysis channels Φ(I + Br), Φ(I + Br\*) and Φ(I\* + Br) to be 0.23, 0.35 and 0.42, respectively, at 267 nm.

**H8. INO (nitrosyl iodide)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The absorption cross sections of INO, nitrosyl iodide, have been measured at room temperature by Porter et al.<sup>3</sup> (390–470 nm), van den Bergh and Troe<sup>4</sup> (around 265 and 410 nm), Basco and Hunt<sup>1</sup> (220–460 nm), and Forte et al.<sup>2</sup> (223–300 nm and around 410 nm). The spectrum shows two absorption bands, a strong and asymmetric band in the UV between 220 and 300 nm with the maximum at 238 nm, and a second weaker band, weaker by two orders of magnitude, between 355 and 470 nm with a maximum near 410 nm. The results for the UV band are in good agreement except for the region around 250 nm, where the absorption spectrum reported by Basco and Hunt<sup>1</sup> shows a hump and an absorption cross section larger by a factor of ~1.5 than that reported by Forte et al.<sup>2</sup> The absorption curve in the near UV and visible reported by Porter et al.<sup>3</sup> is shifted to longer wavelengths by ~20 nm and the absorption cross sections are smaller by 50–30% at 400–430 nm compared to the results of Basco and Hunt.<sup>1</sup>

The recommended absorption cross sections in Table 4H-12 are the mean of the data from Basco and Hunt<sup>1</sup> and Forte et al.<sup>2</sup> for the wavelength range 223–290 nm and the data from Basco and Hunt<sup>1</sup> at 300, 310, and 360 nm. For the wavelength range 360 <  $\lambda$  < 400 nm, the recommended cross sections are smoothed values from Basco and Hunt.<sup>1</sup> For wavelengths > 400 nm, the recommendation is based on the data from van den Berg and Troe,<sup>4</sup> Basco and Hunt,<sup>1</sup> and Forte et al.<sup>2</sup>

**Photolysis Quantum Yield and Product Studies:** The photolysis quantum yield is expected to be unity at wavelengths above the dissociation threshold.

## H9. $\text{INO}_2$ (nitryl iodide)

[Back to Index](#)

(1)

(2)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{INO}_2$ , nitryl iodide, has been measured at room temperature by Bröske<sup>2</sup> over the wavelength range 210–390 nm. The spectrum consists of three broad absorption bands with cross sections of  $4.20 \times 10^{-18}$ ,  $9.6 \times 10^{-19}$ , and  $3.9 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  at 240, 282, and 342 nm, respectively. These values were obtained assuming the stoichiometric conversion of  $\text{NO}_2$  to  $\text{INO}_2$  in the photolysis of  $\text{I}_2\text{-NO}_2$  mixtures. The recommended absorption cross section values in Table 4H-13 were taken from the evaluation by Atkinson et al.<sup>1</sup> Note the cross section values from Bröske<sup>2</sup> quoted in the Mainz spectral atlas<sup>3</sup> differ significantly. On the basis of the mass balance uncertainty in the Bröske study an uncertainty factor of 4 ( $2\sigma$ ) is recommended.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**H10. IONO<sub>2</sub> (iodine nitrate)**[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: JPL10-6)

*Absorption Cross Sections:* The UV absorption spectrum of IONO<sub>2</sub>, iodine nitrate, has been reported by Mössinger et al.<sup>2</sup> (245–415 nm) and Joseph et al.<sup>1</sup> (240–370 nm) using 351 and 248 nm pulsed laser photolysis of NO<sub>2</sub>/CF<sub>3</sub>I/N<sub>2</sub> mixtures, respectively, to produce IONO<sub>2</sub> in the gas-phase. The IONO<sub>2</sub> spectrum consists of a broad continuous absorption band over this wavelength range. There are, however, significant discrepancies between the two studies for the wavelength dependence and absolute absorption cross sections. The reason for the discrepancies in these very similar studies is not known. The recommended cross section values given in Table 4H-14 are taken from Mössinger et al.,<sup>2</sup> however, the uncertainty in the IONO<sub>2</sub> spectrum is large and the lower cross sections reported in the Joseph et al. study can't be ruled out.

*Photolysis Quantum Yield and Product Studies:* The photoproducts of IONO<sub>2</sub> are not well characterized. In the only quantum yield study to date, Joseph et al.<sup>1</sup> report IO and NO<sub>3</sub> quantum yields of  $\Phi(\text{IO}) \leq 0.02$  and  $\Phi(\text{NO}_3) = 0.21 \pm 0.09$  at 248 nm, based on a modeled IONO<sub>2</sub> concentration and their measured cross section at 248 nm. Photolysis is most likely the major daytime loss process for IONO<sub>2</sub> even considering the current large uncertainty in the UV absorption cross sections.

## H11. CH<sub>3</sub>I (methyl iodide)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV and UV absorption spectrum of CH<sub>3</sub>I, methyl iodide, has been measured at room temperature by Rebbert et al.<sup>15</sup> (147 nm), Porret and Goodeve<sup>13</sup> (200–360 nm), Baughcum and Leone<sup>1</sup> (200–310 nm), Pence et al.<sup>12</sup> (180–400 nm), Felps et al.<sup>5</sup> (257.7 nm), Jenkin et al.<sup>6</sup> (205–335 nm), Man et al.<sup>10</sup> (205–360 nm), Kwok and Phillips<sup>8</sup> (192–225 nm), Eden et al.<sup>3</sup> (115–315 nm), Fahr et al.<sup>4</sup> (160–330 nm), Rattigan et al.<sup>14</sup> (235–365 nm), and Roehl et al.<sup>16</sup> (200–350 nm). Kwok and Phillips<sup>8</sup> also measured the CH<sub>3</sub>I spectrum in cyclohexane solution. Fahr et al.<sup>4</sup> also measured the absorption cross sections in the range 330–400 nm in the liquid phase and used a wavelength shift procedure to derive gas-phase cross section values. The temperature dependence of the absorption spectrum has been reported by Fahr et al.<sup>4</sup> (223–333 K), Rattigan et al.<sup>14</sup> (243–333 K), and Roehl et al.<sup>16</sup> (210–298 K). The room temperature cross section data for the wavelength range 210–305 nm are in reasonable to good agreement with Rattigan et al.<sup>14</sup> reporting the smallest and Fahr et al.<sup>4</sup> the largest values. The agreement is generally better than 15% except for the region around the absorption maximum, where the spread is ~30%. Rattigan et al.<sup>14</sup> and Fahr et al.<sup>4</sup> report values of  $1.07 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> and  $1.4 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup>, respectively, for the maximum at ~260 nm. The peak cross section values from the other studies range from  $1.15 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> to  $1.22 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup>. In the wavelength range 305–330 nm, the agreement is within 20%. At wavelengths below 210 nm, the data reported by Jenkin et al.,<sup>6</sup> Roehl et al.,<sup>16</sup> and Kwok and Phillips<sup>9</sup> fit into the strong and highly structured band system reported by Fahr et al.<sup>4</sup> and Eden et al.<sup>3</sup> However, the absorption cross sections reported by Eden et al.<sup>3</sup> in this wavelength range are significantly larger, ~×10. The recommended room temperature absorption cross sections for the wavelength range above 210 nm in Table 4H-15 are the mean of the values reported by Jenkin et al.,<sup>6</sup> Fahr et al.,<sup>4</sup> and Roehl et al.<sup>16</sup> for the range 210–230 nm, the mean of the values reported by Jenkin et al.,<sup>6</sup> Fahr et al.,<sup>4</sup> Rattigan et al.,<sup>14</sup> and Roehl et al.<sup>16</sup> for the range 235–330 nm; the mean of the values reported by Fahr et al.,<sup>4</sup> Rattigan et al.,<sup>14</sup> and Roehl et al.<sup>16</sup> for the range 335–350 nm, and the values of Rattigan et al.<sup>14</sup> for the range 355–365 nm.

Studies of the spectrum temperature dependence are in qualitative agreement with an increase in the peak absorption cross section and decrease in the long wavelength tail cross sections with decreasing temperature. Roehl et al.<sup>16</sup> and Rattigan et al.<sup>14</sup> parameterized the cross section temperature dependence using the empirical expressions

$$\sigma(\lambda, T) = \sigma(298 \text{ K}) [1 + a_1(\lambda)(T-298) + a_2(\lambda)(T-298)^2] \quad (\text{Roehl et al.}^{16})$$

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298) \quad (\text{Rattigan et al.}^{14})$$

Both expressions reproduce the experimental data well and the  $a_1(\lambda)$ ,  $a_2(\lambda)$ , and  $B(\lambda)$  parameters are included in Table 4H-15.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for CH<sub>3</sub>I is expected to be unity for wavelengths above the dissociation threshold. Quantum yields for I\*(<sup>2</sup>P<sub>1/2</sub>) atom formation,  $\Phi(I^*)$ , have been reported by several groups for photolysis between 222 and 333.5 nm. Uma and Das<sup>17–19</sup> reported  $\Phi(I^*)$  values of  $0.63 \pm 0.02$ ,  $0.79 \pm 0.02$ ,  $0.69 \pm 0.02$ , and  $0.43 \pm 0.02$  for 222, 266, 280, and ~305 nm, respectively. Gedanken<sup>19</sup> reported  $\Phi(I^*) = 0.72 \pm 0.08$  at 248 nm. Pence et al.<sup>12</sup> reported  $\Phi(I^*) = 0.81 \pm 0.03$  and ~0.05 at 248 and 308 nm, respectively. Kang et al.<sup>7</sup> reported  $\Phi(I^*) = 0.30$  at 304 nm. Ogorzalek Loo et al.<sup>11</sup> reported  $\Phi(I^*) = 0.47$ , 0.77, and 0.92 at 325.8, 329.4, and 333.5, respectively. Ogorzalek Loo et al.<sup>11</sup> and Brewer et al.<sup>2</sup> have also reported I\* quantum yields for the photolysis of CD<sub>3</sub>I. Quantum yields for I(<sup>2</sup>P<sub>3/2</sub>) atom formation,  $\Phi(I)$ , can be derived from  $\Phi(I) = 1 - \Phi(I^*)$ .

## H12. $\text{CH}_2\text{I}_2$ (diiodomethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{CH}_2\text{I}_2$ , diiodomethane, has been measured at room temperature by Pence et al.<sup>5</sup> (180–400 nm), Schmitt and Comes<sup>7</sup> (220–360 nm), Baughcum and Leone<sup>1</sup> (200–360 nm), Koffend and Leone<sup>2</sup> (265–341 nm), Kwok and Phillips<sup>3</sup> (220–400 nm), Roehl et al.<sup>6</sup> (215–385 nm), and Mössinger et al.<sup>4</sup> (215–385 nm). Kwok and Phillips<sup>3</sup> also measured the  $\text{CH}_2\text{I}_2$  spectrum in methanol and cyclohexane solvents. The temperature dependence of the absorption spectrum has been reported by Roehl et al.<sup>6</sup> (273 and 298 K) and Mössinger et al.<sup>4</sup> (273, 298, and 348 K).

The absorption spectrum shows clear evidence for multiple transitions in the wavelength range 200–400 nm with absorption maxima at ~215, 250, and 290 nm. The room temperature cross section data from the various groups are in good agreement with the exception of Kwok and Phillips;<sup>3</sup> the reported cross sections are within 5 to 10% between 230 and 380 nm. The data from Schmitt and Comes<sup>7</sup> and Koffend and Leone<sup>2</sup> near the 290 nm peak are higher than those of Roehl et al.<sup>6</sup> and Mössinger et al.<sup>4</sup> The values of Kwok and Phillips<sup>3</sup> are lower by 15–20% near 290 nm. The recommended room temperature absorption cross sections in Table 4H-16 are the values from Roehl et al.<sup>6</sup> for the range 205–215 nm, the mean of the values reported by Roehl et al.<sup>6</sup> and Mössinger et al.<sup>4</sup> for the range 220–380 nm, and the value of Mössinger et al.<sup>4</sup> at 385 nm.

The studies of the spectrum temperature dependence are in good agreement with a slight increase in the peak absorption cross section and decrease in the long wavelength tail cross section with decreasing temperature. Mössinger et al.<sup>4</sup> parameterized the cross section temperature dependence between 273 and 348 K using the expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298K) + B(\lambda)(T-298)$$

The  $B(\lambda)$  coefficients are listed in Table 4H-16. (Note: an erroneous  $B$  value at 305 nm was corrected via a personal communication with Dr. Mössinger).

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for  $\text{CH}_2\text{I}_2$  is expected to be unity for wavelengths above the dissociation threshold. Pence et al.<sup>5</sup> have reported quantum yields for  $\text{I}^*(^2\text{P}_{1/2})$  atom formation,  $\Phi(\text{I}^*)$ , at 193, 248, and 308 nm of  $\sim 0.05$ ,  $0.46 \pm 0.04$ , and  $0.25 \pm 0.02$ , respectively. Quantum yields for  $\text{I}(^2\text{P}_{3/2})$  atom formation,  $\Phi(\text{I})$ , can be derived from  $\Phi(\text{I}) = 1 - \Phi(\text{I}^*)$ .

### H13. C<sub>2</sub>H<sub>5</sub>I (iodoethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of C<sub>2</sub>H<sub>5</sub>I, iodoethane, has been measured at room temperature by Rebbert et al.<sup>6</sup> (147 nm,  $\sigma = 1.48 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ ), Porret and Goodeve<sup>4</sup> (205–360 nm), Roehl et al.<sup>7</sup> (205–365 nm), and Rattigan et al.<sup>5</sup> (235–355 nm). The temperature dependence of the absorption spectrum has been reported by Roehl et al.<sup>7</sup> (223–298 K), Rattigan et al.<sup>5</sup> (243–333 K), and Zhang et al.<sup>11</sup> (323 K, 220–320 nm). The room temperature data are in good agreement with the values of Roehl et al.<sup>7</sup> larger than the values of Rattigan et al.<sup>5</sup> by 5–15% over the wavelength range 235–325 nm and 125% at 355 nm. The Rattigan et al.<sup>5</sup> values agree to within 10–15% with the values from Porret and Goodeve.<sup>4</sup> The recommended absorption cross sections in Table 4H-17 are the mean of the values reported by Roehl et al.<sup>7</sup> and Rattigan et al.<sup>5</sup> for the wavelength range 235–355 nm and the data from Roehl et al.<sup>7</sup> in the range 205–230 nm.

Studies of the spectrum temperature dependence by Roehl et al.<sup>7</sup> and Rattigan et al.<sup>5</sup> show that the peak absorption cross section increases with decreasing temperature. The absorption cross sections in the long wavelength tail of the spectrum decrease with decreasing temperature. The data reported by Zhang et al.<sup>11</sup> for 323 K are 10–40% larger around the absorption maximum and as much as 200% larger in the long wavelength tail than the data for 313 and 333 K reported by Rattigan et al.<sup>5</sup> Roehl et al.<sup>7</sup> and Rattigan et al.<sup>5</sup> parameterized the cross section temperature dependence using the empirical expressions

$$\sigma(\lambda, T) = \sigma(298 \text{ K}) [(1 + a_1(\lambda)(T-298) + a_2(\lambda)(T-298)^2)] \quad (\text{Roehl et al.}^7)$$

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298) \quad (\text{Rattigan et al.}^5)$$

Both expressions reproduce the experimental data well and the  $a_1(\lambda)$ ,  $a_2(\lambda)$ , and  $B(\lambda)$  parameters are included in Table 4H-17.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for C<sub>2</sub>H<sub>5</sub>I is expected to be unity for wavelengths above the dissociation threshold. Uma and Das<sup>8-10</sup> have reported quantum yields for I\*(<sup>2</sup>P<sub>1/2</sub>) atom formation,  $\Phi(I^*)$ , at wavelengths between 222 and 305 nm to be  $0.57 \pm 0.02$ ,  $0.72 \pm 0.02$ ,  $0.60 \pm 0.02$ , and  $0.39 \pm 0.02$  at 222, 266, 280, and ~305 nm, respectively. Gedanken<sup>2</sup> report  $\Phi(I^*) = 0.78 \pm 0.07$  at 248 nm. Brewer et al.<sup>1</sup> report  $\Phi(I^*) = 0.68 \pm 0.02$  at 248 nm. Kang et al.<sup>3</sup> report  $\Phi(I^*) = 0.22$  at 304 nm. Quantum yields for I(<sup>2</sup>P<sub>3/2</sub>) atom formation,  $\Phi(I)$ , can be derived from  $\Phi(I) = 1 - \Phi(I^*)$ . Rebbert et al.<sup>6</sup> report that the quantum yield at 147 nm for the overall process C<sub>2</sub>H<sub>5</sub>I + hν → C<sub>2</sub>H<sub>4</sub> + H + I to be 0.75.

**Table 4H-17. Recommended Absorption Cross Sections of C<sub>2</sub>H<sub>5</sub>I at 298 K and Temperature Coefficients**

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of CH<sub>3</sub>CHI<sub>2</sub>, 1,1-diiodoethane, has been measured at 298 K by Schmitt and Comes<sup>1</sup> over the wavelength range 220–360 nm. The continuous spectrum consists of several overlapping transitions with maxima at <220 nm and peaks at 250 and 290 nm. A weaker band appears as a shoulder in the spectrum near 320 nm. The recommended cross sections in Table 4H-18 are taken from Schmitt and Comes.<sup>1</sup>

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for CH<sub>3</sub>CHI<sub>2</sub> is expected to be unity for wavelengths above the dissociation threshold.

## H15. CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>I (1-iodopropane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of 1-C<sub>3</sub>H<sub>7</sub>I, 1-iodopropane, has been measured over the wavelength range 205–335 nm by Roehl et al.<sup>4</sup> for temperatures between 223 and 298 K. The continuous absorption spectrum peaks at 255 nm with evidence for another absorption band at wavelengths <205 nm. A VUV absorption cross section of  $7 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> at 147 nm has been reported by Rebbert et al.<sup>3</sup> The recommended room temperature cross sections for 1-C<sub>3</sub>H<sub>7</sub>I in Table 4H-19 are taken from Roehl et al.<sup>4</sup>

The absorption cross section near the peak increases with decreasing temperature. The cross sections in the long wavelength tail decrease with decreasing temperature. Roehl et al.<sup>4</sup> parameterized the temperature dependence using the empirical expression

$$\sigma(\lambda, T) = \sigma(298 \text{ K}) [1 + a_1(\lambda)(T-298) + a_2(\lambda)(T-298)^2]$$

The a<sub>1</sub>(λ) and a<sub>2</sub>(λ) parameters are included in Table 4H-19.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for 1-C<sub>3</sub>H<sub>7</sub>I is expected to be unity for wavelengths above the dissociation threshold. Uma and Das<sup>5,6</sup> report quantum yields for I\*({}^2\text{P}\_{1/2}) atom formation, Φ(I\*), at several photolysis wavelengths to be  $0.54 \pm 0.02$ ,  $0.66 \pm 0.02$ ,  $0.56 \pm 0.02$ , and  $0.35 \pm 0.02$  at 222, 266, 280, and ~305 nm, respectively. Brewer et al.<sup>1</sup> report  $\Phi(I^*) = 0.60 \pm 0.02$  at 248 nm. Kang et al.<sup>2</sup> report  $\Phi(I^*) = 0.20$  at 304 nm. Quantum yields for I({}^2\text{P}\_{3/2}) atom formation, Φ(I), can be derived from  $\Phi(I) = 1 - \Phi(I^*)$ . At 147 nm, Rebbert et al.<sup>3</sup> report quantum yields for the overall processes 1-C<sub>3</sub>H<sub>7</sub>I + hv → C<sub>3</sub>H<sub>6</sub> + H + I and 1-C<sub>3</sub>H<sub>7</sub>I + hv → CH<sub>3</sub> + C<sub>2</sub>H<sub>4</sub> + I to be 0.38 and 0.47, respectively.

**Table 4H-19. Recommended Absorption Cross Sections of C<sub>3</sub>H<sub>7</sub>I at 298 K and Temperature Coefficients**

$\lambda$ (nm)	1-C <sub>3</sub> H <sub>7</sub> I			2-C <sub>3</sub> H <sub>7</sub> I		
	10 <sup>20</sup> $\sigma$ (cm <sup>2</sup> )	10 <sup>3</sup> a <sub>1</sub> (K <sup>-1</sup> )	10 <sup>5</sup> a <sub>2</sub> (K <sup>-2</sup> )	10 <sup>20</sup> $\sigma$ (cm <sup>2</sup> )	10 <sup>3</sup> a <sub>1</sub> (K <sup>-1</sup> )	10 <sup>5</sup> a <sub>2</sub> (K <sup>-2</sup> )

## H16. CH<sub>3</sub>CHICH<sub>3</sub> (2-iodopropane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of 2-C<sub>3</sub>H<sub>7</sub>I, 2-iodopropane, has been measured by Roehl et al.<sup>4</sup> (223–298 K and 205–380 nm) and Phillips et al.<sup>2</sup> (298 K, 235–305 nm). Phillips et al.<sup>2</sup> also report an absorption spectrum of 2-C<sub>3</sub>H<sub>7</sub>I in a cyclohexane solution. The continuous absorption spectrum peaks at 260 nm with evidence for another absorption band at wavelengths <205 nm. The gas-phase data reported by Phillips et al.<sup>2</sup> are larger by 30–70% over the entire absorption band than the data from Roehl et al.<sup>4</sup> A room temperature cross section of  $7.59 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 147 nm has been reported by Rebbert et al.<sup>3</sup> The recommended room temperature values for 2-C<sub>3</sub>H<sub>7</sub>I in Table 4H-19 are taken from Roehl et al.<sup>4</sup>

The absorption cross section near the peak increases with decreasing temperature. The cross sections in the long-wavelength tail decrease with decreasing temperature. Roehl et al.<sup>4</sup> parameterized the temperature dependence using the empirical expression

$$\sigma(\lambda, T) = \sigma(298 \text{ K}) [1 + a_1(\lambda)(T-298) + a_2(\lambda)(T-298)^2]$$

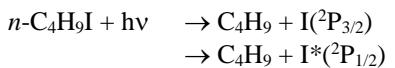

The a<sub>1</sub>(λ) and a<sub>2</sub>(λ) parameters are included in Table 4H-19.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for 2-C<sub>3</sub>H<sub>7</sub>I is expected to be unity for wavelengths above the dissociation threshold. Uma and Das<sup>5</sup> report quantum yields for I\*( $^2\text{P}_{1/2}$ ) atom formation, Φ(I\*), at several wavelengths to be 0.40 ± 0.02, 0.44 ± 0.03, and 0.19 ± 0.02 at 222, 266, and ~305 nm, respectively. Brewer et al.<sup>1</sup> report Φ(I\*) = 0.26 ± 0.02 at 248 nm. Quantum yields for I( $^2\text{P}_{3/2}$ ) atom formation, Φ(I), can be derived from Φ(I) = 1 - Φ(I\*). At 147 nm, Rebbert et al.<sup>3</sup> report quantum yields for the overall processes 2-C<sub>3</sub>H<sub>7</sub>I + hv → C<sub>3</sub>H<sub>6</sub> + H + I and 2-C<sub>3</sub>H<sub>7</sub>I + hv → CH<sub>3</sub> + C<sub>2</sub>H<sub>4</sub> + I to be 0.80 and 0.07.

## H17. n-C<sub>4</sub>H<sub>9</sub>I (n-butyl iodide)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Absorption cross sections for n-C<sub>4</sub>H<sub>9</sub>I, n-butyl iodide, are not available.

*Photolysis Quantum Yield and Product Studies:* The quantum yield of n-C<sub>4</sub>H<sub>9</sub>I for UV photolysis is expected to be unity. Quantum yields for I\*( $^2\text{P}_{1/2}$ ) atom formation has been reported by Uma and Das<sup>3,4</sup> to be 0.51 ± 0.02, 0.64 ± 0.03, 0.50 ± 0.03, and 0.30 ± 0.02 at 222, 266, 280, and ~305 nm, respectively. Brewer et al.<sup>1</sup> and Kang et al.<sup>2</sup> have reported quantum yields for I\*( $^2\text{P}_{1/2}$ ) of 0.53 ± 0.03 and = 0.14 at 248 nm and 304 nm, respectively.

- (1) Brewer, P.; Das, P.; Ondrey, G.; Bersohn, R. Measurement of the relative populations of I( $^2\text{P}_{1/2}$ ) and I( $^2\text{P}_{3/2}$ ) by laser induced vacuum ultraviolet fluorescence. *J. Chem. Phys.* **1983**, *79*, 720-723.

- (4) Uma, S.; Das, P. K. Production of  $\text{I}^*({}^2\text{P}_{1/2})$  in the ultraviolet photodissociation of  $\alpha$ -branched alkyl iodides. *J. Chem. Phys.* **1996**, *104*, 4470-4474.

#### H18. $(\text{CH}_3)_2\text{CHCH}_2\text{I}$ (*iso*-butyl iodide)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Absorption cross sections for *iso*- $\text{C}_4\text{H}_9\text{I}$ , *iso*-butyl iodide, are not available.

*Photolysis Quantum Yield and Product Studies:* The quantum yield of *iso*- $\text{C}_4\text{H}_9\text{I}$  for UV photolysis is expected to be unity. The  $\text{I}^*({}^2\text{P}_{1/2})$  atom quantum yield,  $\Phi(\text{I}^*({}^2\text{P}_{1/2}))$ , has been shown to be wavelength dependent with lower yields at longer photolysis wavelengths. Uma and Das<sup>2</sup> reported  $\Phi(\text{I}^*({}^2\text{P}_{1/2}))$  values of  $0.71 \pm 0.01$ ,  $0.56 \pm 0.03$ , and  $0.35 \pm 0.02$ , at 266, 280, and  $\sim 305$  nm, respectively. Brewer et al.<sup>1</sup>, however, reported a significantly lower value of  $\Phi(\text{I}^*({}^2\text{P}_{1/2}))$  at 248 nm,  $0.20 \pm 0.02$ .

- (1) Brewer, P.; Das, P.; Ondrey, G.; Bersohn, R. Measurement of the relative populations of  $\text{I}({}^2\text{P}_{1/2}^0)$  and  $\text{I}({}^2\text{P}_{3/2}^0)$  by laser induced vacuum ultraviolet fluorescence. *J. Chem. Phys.* **1983**, *79*, 720-723.
- (2) Uma, S.; Das, P. K. Production of  $\text{I}^*({}^2\text{P}_{1/2})$  in the ultraviolet photodissociation of  $\alpha$ -branched alkyl iodides. *J. Chem. Phys.* **1996**, *104*, 4470-4474.

#### H19. $(\text{CH}_3)_3\text{Cl}$ (*tert*-butyl iodide)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of *tert*- $\text{C}_4\text{H}_9\text{I}$ , *tert*-butyl iodide, at 323 K has been reported by Phillips et al.<sup>5</sup> (230–310 nm). The spectrum is continuous and shows a single absorption band with a peak cross section of  $\sim 2.1 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  at  $\sim 268$  nm. The recommended absorption cross sections in Table 4H-20 were taken from a figure given in Phillips et al.,<sup>5</sup> as reported in the Mainz spectral atlas.<sup>3</sup>

*Photolysis Quantum Yield and Product Studies:* Quantum yields for I atom formation in the photolysis of *tert*- $\text{C}_4\text{H}_9\text{I}$  have been reported by Kim et al.<sup>4</sup> to be  $\Phi(\text{I}({}^2\text{P}_{3/2}) + \text{I}^*({}^2\text{P}_{1/2})) = 0.93$  and  $0.92$  at 277 and 304 nm, respectively. On the basis of this study a *tert*- $\text{C}_4\text{H}_9\text{I}$  photolysis quantum yield of unity is recommended for wavelengths  $< 310$  nm. The  $\text{I}^*({}^2\text{P}_{1/2})$  atom quantum yield,  $\Phi(\text{I}^*({}^2\text{P}_{1/2}))$ , has been shown to be wavelength dependent with lower yields for photolysis at the longer wavelengths. Uma and Das<sup>6</sup> reported values for  $\Phi(\text{I}^*({}^2\text{P}_{1/2}))$  of  $0.33 \pm 0.03$ ,  $0.20 \pm 0.03$ , and  $0.12 \pm 0.03$  at 222, 266, and  $\sim 305$  nm, respectively. Gedanken<sup>2</sup> reported  $\Phi(\text{I}^*({}^2\text{P}_{1/2})) = 0.41 \pm 0.10$  for 248 nm photolysis. Brewer et al.<sup>1</sup> reported a much lower value,  $0.03 \pm 0.02$ , for photolysis at 248 nm in disagreement with the other studies.

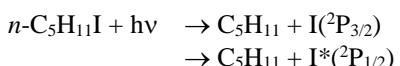

**Table 4H-20. Recommended Absorption Cross Sections of  $(CH_3)_3Cl$  at 323 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm $^2$ )

**H21. CF<sub>3</sub>I (trifluoriodomethane)**[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of CF<sub>3</sub>I, trifluoriodomethane, has been reported in a number of studies as summarized in Table 4H-21. The spectrum is continuous between 180 and 400 nm with a strong band centered at 267 nm with a long wavelength tail and a strong band evident at wavelengths <200 nm. The agreement among the room temperature cross section values at wavelengths >200 nm is better than 20% near the absorption maximum. At wavelengths <255 nm and in the range 280–350 nm the agreement is better than 15%. Fahr et al.<sup>6</sup> report the largest peak cross section and Rattigan et al.<sup>14</sup> the smallest. The cross section data from Solomon et al.<sup>16</sup> become increasingly greater than those of Rattigan et al.<sup>14</sup> at the longer wavelengths. The cross section data from Limão-Vieira et al.<sup>13</sup> lie between the data of Solomon et al.<sup>16</sup> and Fahr et al.<sup>6</sup> For wavelengths <230 nm and >310 nm the Limão-Vieira et al.<sup>13</sup> data shows systematic deviations from the other studies. The recommended absorption cross sections in Table 4H-22 are taken from the data of Fahr et al.<sup>6</sup> in the range 180–215 nm, the mean of the values reported by Brouwer and Troe,<sup>5</sup> Solomon et al.,<sup>16</sup> and Fahr et al.<sup>6</sup> in the range 220–230 nm, the mean of the values reported by Brouwer and Troe,<sup>5</sup> Solomon et al.,<sup>16</sup> Fahr et al.,<sup>6</sup> and Rattigan et al.<sup>14</sup> in the range 235–310 nm, the mean of the values reported by Solomon et al.,<sup>16</sup> Fahr et al.,<sup>6</sup> and Rattigan et al.<sup>14</sup> in the range 315–350 nm, and the values from Rattigan et al.<sup>14</sup> in the range 355–385 nm.

**Table 4H-21. Summary of CF<sub>3</sub>I Absorption Cross Section Studies**

Study	Year	Temperature (K)	Wavelength (nm)	10 <sup>20</sup> σ(267 nm) (cm <sup>2</sup> )
Roxlo and Mandl <sup>15</sup>	1980	298	170–230	—
Brouwer and Troe <sup>5</sup>	1981	298, 625, 1050	220–360	~60.5
Bagratashvili et al. <sup>3</sup> and Abel et al. <sup>1,2</sup>	1985	~4000 *	450	—
Solomon et al. <sup>16</sup>	1994	200–298	216–370	64.4
Fahr et al. <sup>6</sup>	1995	218–333	160–350	~70
Rattigan et al. <sup>14</sup>	1997	243–333	235–390	59.5
Limão-Vieira et al. <sup>13</sup>	2003	298	205–325 113–181	66.9

\* CF<sub>3</sub>I molecules excited by infrared laser absorption

Fahr et al.<sup>6</sup> (160–350 nm) and Limão-Vieira et al.<sup>13</sup> (113–181 nm) reported spectra with pronounced band structure and large absorption cross sections in the short wavelength region. The maximum absorption cross section reported was ~1 × 10<sup>-16</sup> cm<sup>2</sup> molecule<sup>-1</sup> at ~160 nm. The spectrum reported by Roxlo and Mandl<sup>15</sup> (170–230 nm) is in poor agreement with the results of Fahr et al.<sup>6</sup> and Limão-Vieira et al.<sup>13</sup>

Studies of the spectrum temperature dependence by Solomon et al.,<sup>16</sup> Fahr et al.,<sup>6</sup> and Rattigan et al.<sup>14</sup> are in qualitative agreement with an increase in the peak absorption cross section and decrease in the long wavelength tail cross sections (>280 nm) with decreasing temperature. The ratio σ(298 K)/σ(~240 K) at 267 nm is ~0.9 and the ratio σ(333 K)/σ(298 K) is ~1. Solomon et al.<sup>16</sup> report a further increase of the peak cross section down to 200 K, whereas Fahr et al.<sup>6</sup> report a slight decrease between 253 and 218 K. The ratio σ(298 K)/σ(~240 K) increases from ~1.0 to ~1.9 between 280 and 340 nm and the ratio σ(333 K)/σ(298 K) is nearly constant at ~1.3. In the wavelength region 160–180 nm, Fahr et al.<sup>6</sup> report a decrease in the absorption cross sections with decreasing temperature. Solomon et al.<sup>16</sup> and Rattigan et al.<sup>14</sup> parameterized the cross section temperature dependence using the empirical expression

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T - 298)$$

which reproduces the experimental data reasonably well. Fahr et al.<sup>6</sup> parameterized their measured cross section wavelength dependence using the empirical expression

$$\sigma(\lambda) = \sigma_0(\lambda) \exp(-L/\lambda) \text{ for } \lambda > 320 \text{ nm}$$

and the temperature dependence at 300, 310, 320, 330, 340, and 350 nm using

$$\sigma(T) = \sigma_0(T) \exp(-\theta/T)$$

Their paper should be consulted for the optimized σ<sub>0</sub>(λ), L, σ<sub>0</sub>(T) and θ parameters. There are some systematic differences in the B(λ) coefficients reported by Solomon et al.<sup>16</sup> and Rattigan et al.<sup>14</sup> The B(λ) coefficients reported by Rattigan et al.<sup>14</sup> are recommended and listed in Table 4H-22.

**Photolysis Quantum Yield and Product Studies:** The photolysis quantum yield for CF<sub>3</sub>I is expected to be unity for wavelengths above the dissociation threshold. CF<sub>3</sub>I serves as a model system for the study of the photodynamics of I\*(<sup>2</sup>P<sub>1/2</sub>) atom production following UV photolysis of iodine containing molecules. There are a number of studies reporting iodine spin-state quantum yields,  $\Phi(I^*(^2P_{1/2}))$  and  $\Phi(I(^2P_{3/2}))$ . A summary of the quantum yield studies for photolysis in the wavelength range 248–308 nm is given in Table 4H-23. Quantum yields for I(<sup>2</sup>P<sub>3/2</sub>) atom formation,  $\Phi(I)$ , can be derived from  $\Phi(I) = 1 - \Phi(I^*)$ .

## H22. CF<sub>2</sub>I<sub>2</sub> (difluorodiiodomethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The room temperature UV absorption spectrum of CF<sub>2</sub>I<sub>2</sub>, difluorodiiodomethane, has been measured by Wannenmacher et al.<sup>3</sup> and Baum et al.<sup>1</sup> over the wavelength range 190–420 nm. The spectrum consists of a strong band that peaks at ~195 nm and several weaker overlapping absorption bands between 230 and 400 nm. The overlapping bands suggest transitions corresponding to the different dissociation processes. Numerical cross section data was obtained from the Mainz spectral atlas.<sup>2</sup> The recommended absorption cross sections in Table 4H-24 are from Wannenmacher et al.<sup>3</sup> and were normalized to a peak value of  $2.929 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  at 300 nm. The peak cross section was derived from five different spectra and has an uncertainty of  $\pm 16\%$ .

*Photolysis Quantum Yield and Product Studies:* The photodissociation of CF<sub>2</sub>I<sub>2</sub> has been studied at room temperature and wavelengths 248, 308, 337, and 351 nm by Wannenmacher et al.<sup>3</sup> and Baum et al.<sup>1</sup> These studies report a competition between the radical channel, CF<sub>2</sub>I + I, and a three body dissociation channel to form CF<sub>2</sub> + I + I. The spin-orbit branching ratio, I<sup>\*</sup>(<sup>2</sup>P<sub>1/2</sub>)/I(<sup>2</sup>P<sub>3/2</sub>) was observed to increase at shorter photolysis wavelengths.

## H23. $\text{C}_2\text{F}_5\text{I}$ (pentafluoroiodoethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of  $\text{C}_2\text{F}_5\text{I}$ , pentafluoroiodoethane, was measured at 323 K by Zhang et al.<sup>4</sup> over the wavelength range 220–320 nm. The continuous absorption band has a maximum at ~269 nm with a cross section of  $\sim 6.7 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ . Pence et al.<sup>3</sup> report a slightly smaller cross section of  $6.39 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  at 268 nm and 295 K. The recommended values in Table 4H-25 were obtained from a figure in Zhang et al.,<sup>4</sup> as reported in the Mainz spectral atlas.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for  $\text{C}_2\text{H}_5\text{I}$  is expected to be unity for wavelengths above the dissociation threshold. Kavita and Das<sup>1</sup> reported quantum yields for  $\text{I}^*({}^2\text{P}_{1/2})$  atom formation,  $\Phi(\text{I}^*)$ , at 266, 288, and ~305 nm to be  $0.97 \pm 0.03$ ,  $0.75 \pm 0.03$ , and  $0.83 \pm 0.05$ , respectively. Quantum yields for  $\text{I}({}^2\text{P}_{3/2})$  atom formation,  $\Phi(\text{I})$ , can be derived from  $\Phi(\text{I}) = 1 - \Phi(\text{I}^*)$ .

#### **H24. *n*-C<sub>3</sub>F<sub>7</sub>I (*n*-heptafluoropropyl iodide)**

[Back to Index](#)

(2)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** The UV absorption spectrum of *n*-C<sub>3</sub>F<sub>7</sub>I, *n*-heptafluoropropyl iodide, has been measured at room temperature by Koffend and Leone<sup>2</sup> (265–341 nm) and Pence et al.<sup>3</sup> (180–400 nm). Pence et al.<sup>3</sup> report a plot (in arbitrary units) that shows an absorption band between ~220 and 340 nm with the maximum at ~268 nm. They report absolute absorption cross sections at 248, 268, and 308 nm. The data for 268 and 308 nm are in good agreement with the corresponding data reported by Koffend and Leone. The recommended absorption cross sections in Table 4H-26 include the value at 248 nm reported by Pence et al.,<sup>3</sup> the mean of the values from Pence et al. and Koffend and Leone at 268 nm, and values from Koffend and Leone for the wavelength range 270–340 nm (values obtained by interpolation and extrapolation).

**Photolysis Quantum Yield and Product Studies:** The quantum yield for n-C<sub>3</sub>F<sub>7</sub>I at wavelengths above the dissociation threshold is expected to be unity. Kavita and Das<sup>1</sup> reported quantum yields for I\*(<sup>2</sup>P<sub>1/2</sub>) atom formation,  $\Phi(I^*)$ , of 0.83 ± 0.02, 0.89 ± 0.03, and 0.90 ± 0.05 at 266, 288, and ~305 nm, respectively. They also report  $\Phi(I^*)$  = 0.83 ± 0.01, 0.80 ± 0.03, and 0.89 ± 0.02 for 2-C<sub>3</sub>F<sub>7</sub>I at 266, 288, and ~305 nm, respectively. Quantum yields for I(<sup>2</sup>P<sub>3/2</sub>) atom formation,  $\Phi(I)$ , can be derived from  $\Phi(I) = 1 - \Phi(I^*)$ .

## H26. *n*-C<sub>6</sub>F<sub>13</sub>I (perfluorohexyl iodide)

[Back to Index](#)

(1)

(2)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Absorption cross sections for *n*-C<sub>6</sub>F<sub>13</sub>I, perfluorohexyl iodide, are not available.

*Photolysis Quantum Yield and Product Studies:* The quantum yield for *n*-C<sub>6</sub>F<sub>13</sub>I at wavelengths above the dissociation threshold is expected to be unity. Kavita and Das<sup>1</sup> report quantum yields for I<sup>\*</sup>( $^2P_{1/2}$ ) atom formation,  $\Phi(\text{I}^*)$ , of  $0.82 \pm 0.02$ ,  $0.74 \pm 0.03$ , and  $0.82 \pm 0.01$  at 266, 288, and  $\sim$ 305 nm, respectively. Quantum yields for I( $^2P_{3/2}$ ) atom formation,  $\Phi(\text{I})$ , can be derived from  $\Phi(\text{I}) = 1 - \Phi(\text{I}^*)$ .

## H27. CH<sub>2</sub>ICl (chloroiodomethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of CH<sub>2</sub>ICl, chloroiodomethane, at room temperature has been reported by Schmitt and Comes<sup>5</sup> (205–330 nm), Kwok and Phillips<sup>1,2</sup> (192–225 nm and 215–400 nm), Roehl et al.<sup>4</sup> (205–355 nm), and Rattigan et al.<sup>3</sup> (235–390 nm). Kwok and Phillips also measured the CH<sub>2</sub>ICl spectrum in cyclohexane solution. Schmitt and Comes<sup>5</sup> and Kwok and Phillips<sup>1,2</sup> have only given their data as plots and are not considered further in this evaluation. Roehl et al.<sup>4</sup> (223–298 K) and Rattigan et al.<sup>3</sup> (243–333 K) have also reported cross section data over a range of temperatures. The room temperature data of Roehl et al. and Rattigan et al. are in good agreement with the values from Rattigan et al. being lower by  $\leq$ 10% between 240 and 345 nm. The recommended absorption cross sections in Table 4H-27 are from Roehl et al. for the wavelength range 205–230 nm, the mean of the values reported by Roehl et al. and Rattigan et al. for the range 235–355 nm, and from Rattigan et al.<sup>3</sup> for the range 360–390 nm.

The cross section data from Roehl et al. and Rattigan et al. show an increase in absorption cross sections around the absorption peak ( $\sim$ 250–285 nm) with decreasing temperature. An opposite effect was reported for wavelengths  $>$ 285 nm. The peak cross section at  $\sim$ 250 K reported in the two studies agree to within 15%. Roehl et al. and Rattigan et al. parameterized the cross section temperature dependence using different empirical expressions

$$\sigma(\lambda, T) = \sigma(298 \text{ K}) [1 + a_1(\lambda)(T-298) + a_2(\lambda)(T-298)^2] \text{ (Roehl et al.)}$$

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298) \text{ (Rattigan et al.)}$$

Both expressions reproduce the experimental data well and the  $a_1(\lambda)$ ,  $a_2(\lambda)$ , and  $B(\lambda)$  coefficients are given in Table 4H-27.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for CH<sub>2</sub>ICl is expected to be unity for wavelengths above the dissociation threshold. The quantum yield branching ratio I\*(<sup>2</sup>P<sub>1/2</sub>)/(I(<sup>2</sup>P<sub>3/2</sub>) + I\*(<sup>2</sup>P<sub>1/2</sub>)) has been reported by Senapati et al.<sup>7</sup> at 5 wavelengths to be 0.47 ± 0.02 at 222 nm, 0.51 ± 0.01 at 236 nm, 0.51 ± 0.02 at 266 nm, 0.55 ± 0.03 at 280 nm, and 0.38 ± 0.01 at 304 nm. The quantum yield branching ratio Cl\*(<sup>2</sup>P<sub>1/2</sub>)/(Cl(<sup>2</sup>P<sub>3/2</sub>) + Cl\*(<sup>2</sup>P<sub>1/2</sub>)) was reported by Senapati and Das<sup>6</sup> at 4 wavelengths to be 0.44 at 222 nm, 0.44 at 266 nm, 0.30 at 280 nm, and 0.22 at 304 nm.

## H28. $\text{CH}_2\text{BrI}$ (bromoiodomethane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption cross sections of  $\text{CH}_2\text{BrI}$ , bromoiodomethane, have been measured at room temperature by Man et al.<sup>1</sup> (180–360 nm) and at 273, 298, and 348 K by Mössinger et al.<sup>2</sup> (215–390 nm). The spectrum exhibits two absorption bands with maxima near 210 and 267 nm that can be assigned to electronic transitions to repulsive states anti-bonding in C–Br and C–I, respectively. The results from the two studies are not in quantitative agreement. Mössinger et al. report room temperature absorption cross sections of  $5.7 \times 10^{-18}$  and  $2.3 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> at 215 and 270 nm, whereas Man et al. give larger values of  $\sim 1 \times 10^{-17}$  and  $3.5 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> at these wavelengths (values extracted from a figure in their paper), respectively. The recommended room temperature cross sections in Table 4H-28 are taken from Mössinger et al. The absorption cross sections increase with decreasing temperature around the band maxima and decrease in the long wavelength tail, in the region 220–240 nm, and above 290 nm. Mössinger et al. parameterized the temperature dependence using the empirical relation

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298)$$

The B( $\lambda$ ) coefficients are listed in Table 4H-28 (an erroneous B value at 280 nm has been corrected).

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for wavelengths above the dissociation threshold is expected to be unity.

**H29. CF<sub>2</sub>BrCF<sub>2</sub>I (1,1,2,2-tetrafluoro-1,2-bromoiodoethane)**[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The absorption spectrum of CF<sub>2</sub>BrCF<sub>2</sub>I, 1,1,2,2-tetrafluoro-1,2-bromoiodoethane, has been measured at room temperature over the wavelength range 190–350 nm by Pence et al.<sup>1</sup> The absorption spectrum shows two distinct bands with a maxima near 268 nm that corresponds to excitation in the C–I bond and below 193 nm that corresponds to excitation in the C–Br bond. An absorption cross section of  $2.36 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  at 193 nm was reported. The recommended cross sections in Table 4H-29 were taken from a figure in Pence et al.<sup>1</sup> and normalized to the quoted 193 nm cross section value.

*Photolysis Quantum Yield and Product Studies:* The quantum yield for CF<sub>2</sub>BrCF<sub>2</sub>I photolysis is assumed to be unity for wavelengths <350 nm. A quantum yield for Br atom formation in the excited (<sup>2</sup>P<sub>1/2</sub>) spin state of  $0.07 \pm 0.05$  at 193 nm was reported by Pence et al.<sup>1</sup>

## SECTION 4I. SO<sub>x</sub> PHOTOCHEMISTRY

### II. SO<sub>2</sub> (sulfur dioxide)

[Back to Index](#)

(Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of sulfur dioxide, SO<sub>2</sub>, is highly structured with a very weak absorption band in the 340–390 nm region, an absorption band in the 260–340 nm region, and a strong absorption band extending from 180 to 235 nm. For the wavelength region commonly used for atmospheric monitoring, 300–324 nm, there are numerous reports of room temperature absorption cross sections. Manatt and Lane<sup>8</sup> have compiled and evaluated SO<sub>2</sub> cross section measurements prior to 1993 that cover the wavelength range 106–403 nm. Since 1993 there have been additional studies including Bogumil et al.<sup>1</sup> (239–395 nm), Feng et al.<sup>3</sup> (7.7–248 nm), Hermans et al.<sup>5</sup> (227–416 nm), Prahlad and Kumar<sup>10</sup> (188–219 nm), Rufus et al.<sup>11</sup> (220–325 nm), Sprague and Joens<sup>12</sup> (352–396 nm), Vandaele et al.<sup>13</sup> (250–333 nm), Vattulainen et al.<sup>14</sup> (195–350 nm), and Wu et al.<sup>15</sup> (170–297 nm). The temperature dependence of the absorption spectrum has been measured by McGee and Burris<sup>9</sup> (295 and 210 K), Bogumil et al.<sup>1</sup> (203–293 K), Hicks<sup>6</sup> (199–300 K), Hermans et al.<sup>5</sup> (298–358 K), Leroy et al.<sup>7</sup> (218–296 K), Prahlad and Kumar<sup>10</sup> (220–300 K), Vattulainen et al.<sup>14</sup> (293–1073 K), and Wu et al.<sup>15</sup> (200–400 K). Absorption cross sections are not recommended due to the highly structured nature of the spectrum and should be obtained from the original literature.

*Photolysis Quantum Yield and Product Studies:* The atmospheric photochemistry of SO<sub>2</sub> has been reviewed by Heicklen et al.<sup>4</sup> and Calvert and Stockwell.<sup>2</sup> Photo-oxidation at  $\lambda > \sim 300$  nm by way of the electronically excited states of SO<sub>2</sub> appears to be relatively unimportant.

## I2. SO<sub>3</sub> (sulfur trioxide)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The VUV/UV absorption spectrum of sulfur trioxide, SO<sub>3</sub>, is continuous between 140 and 330 nm with weak vibrational band structure superimposed between 222 and 285 nm. Absorption cross sections have been reported by Leroy et al.<sup>3</sup> (240–264 nm), Burkholder and McKeen<sup>1</sup> (196–330 nm), and Hintze et al.<sup>2</sup> (140–194 nm). The cross section values are in good agreement in the regions of overlap and the recommended cross sections between 180 and 330 nm in Table 4I-1 are taken from Burkholder et al.<sup>1</sup> and Hintze et al.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* No recommendation.

**Table 4I-1. Recommended Absorption Cross Sections of SO<sub>3</sub> at 298 K**

**I3. H<sub>2</sub>S (hydrogen sulfide)**[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of hydrogen sulfide, H<sub>2</sub>S, is weak at wavelengths >250 nm. H<sub>2</sub>S has a strong absorption band with diffuse structure centered near 200 nm and a broad VUV spectrum. The H<sub>2</sub>S absorption cross section at 184.9 nm has been measured by Wine et al.<sup>3</sup> to be  $3.82 \times 10^{-18}$  cm<sup>2</sup> molecule<sup>-1</sup> and at 121.6 nm by Watanabe and Jursa<sup>2</sup> and Vatsa and Volpp<sup>1</sup> to be  $2.65 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup> (average value). The recommended absorption cross sections in Table 4I-2 are taken from Wu and Chen.<sup>4</sup> Note that the values given here do not reproduce the full detail of the diffuse band structure.

*Photolysis Quantum Yield and Product Studies:* Photolysis is a minor atmospheric loss process for H<sub>2</sub>S throughout the troposphere and stratosphere.

**Table 4I-2. Recommended Absorption Cross Sections of H<sub>2</sub>S at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )	$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )

**I4. H<sub>2</sub>SO<sub>4</sub> (sulfuric acid)**[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The gas-phase absorption spectrum of sulfuric acid, H<sub>2</sub>SO<sub>4</sub>, was reported by Burkholder et al.<sup>1</sup> (195–330 nm) at 473 K, using diode array spectroscopy, to have cross sections  $<1 \times 10^{-21}$  cm<sup>2</sup> molecule<sup>-1</sup>. Hintze et al.<sup>2</sup> studied the spectrum of H<sub>2</sub>SO<sub>4</sub> vapor at 403–423 K and reported an upper limit

of  $1 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  for the absorption cross sections between 140 and 170 nm and an upper limit of  $1 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  in the wavelength range 170–195 nm.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

- (1) Burkholder, J. B.; Mills, M.; McKeen, S. Upper limit for the UV absorption cross sections of H<sub>2</sub>SO<sub>4</sub>. *Geophys. Res. Lett.* **2000**, 27, 2493–2496.

## 15. CS<sub>2</sub> (carbon disulfide)

[Back to Index](#)

(Recommendation: 10-6, Note: 15-10, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of carbon disulfide, CS<sub>2</sub>, has two distinct highly structured bands with a strong absorption extending from 185 to 230 nm and a weaker band in the 290–380 nm range. The absorption cross sections have been measured in a number of studies (Cook and Ogawa<sup>4</sup> (60–96.5 nm, 298 K), Carnovale et al.<sup>2</sup> (31–248 nm, 298 K), Leroy et al.<sup>8</sup> (314–330 nm, 294 K), Leroy et al.<sup>9</sup> (314–330 nm, 197–288 K), Wine et al.<sup>12</sup> (280–360 nm, 298 K), Wu and Judge<sup>13</sup> (319–330 nm, 294 K), Dove et al.<sup>5</sup> (190–500 nm, 300–4000 K), Hearn and Joens<sup>7</sup> (296–334 nm, 300 K), Ahmed and Kumar<sup>1</sup> (188–340 nm, 300 K), Xu and Joens<sup>14</sup> (187–220 nm, 300 K), Chen and Wu<sup>3</sup> (180–228 nm, 295 K), Grosch et al.<sup>6</sup> (195–370 nm, 295–773 K), and Sunanda et al.<sup>11</sup> (105–226 nm, 298 K)), which are in reasonable agreement. Due to the high degree of structure in the absorption spectrum, absorption cross sections at specific wavelengths should be obtained from the original literature. The absorption cross sections in Table 4I-3 were obtained by averaging the data from Hearn and Joens<sup>7</sup> over 1 nm intervals.

*Photolysis Quantum Yield and Product Studies:* The photochemistry of CS<sub>2</sub> has been reviewed by Okabe<sup>10</sup> and discussed by Wine et al.<sup>12</sup> Wine et al. report that electronically excited CS<sub>2</sub> may react with O<sub>2</sub> to yield OCS.

**Table 4I-3. Recommended Absorption Cross Sections of CS<sub>2</sub> at 298 K**

## I6. OCS (carbonyl sulfide)

[Back to Index](#)

OCS + hν → CO + S( <sup>3</sup> P)	308.4 kJ mol <sup>-1</sup>	388 nm	(1)
→ CO + S( <sup>1</sup> D)	418.4 kJ mol <sup>-1</sup>	285 nm	(2)
→ CO + S( <sup>1</sup> S)	573.2 kJ mol <sup>-1</sup>	209 nm	(3)

(Recommendation: 82–57, Note: 10–6, Evaluated: 10–6)

*Absorption Cross Sections:* The UV absorption spectrum of carbonyl sulfide, OCS, peaks near 222 nm with weak diffuse structure near the peak and in the long wavelength tail that is superimposed on a stronger continuum. The absorption cross sections of OCS have been measured at room temperature by Breckenridge and Taube<sup>1</sup> (200–260 nm), Rudolph and Inn<sup>5</sup> (200–270 nm), Leroy et al.<sup>3</sup> (210–260 nm), Ferro and Ruben<sup>2</sup> (210–250 nm), Wu<sup>6</sup> (200–252 nm), and Molina et al.<sup>4</sup> (185–300 nm). The reported peak absorption cross sections agree to within 15%. The absorption spectrum temperature dependence has been measured by Wu<sup>6</sup> (170–370 K), Rudolph and Inn<sup>5</sup> (195 K), and Molina et al.<sup>4</sup> (225 K). The OCS spectrum shows a decrease in absolute cross section with decreasing temperature at all wavelengths between 210–300 nm. The recommended cross sections in Table 4I-4 are the values averaged over the wavelength intervals used in solar photolysis calculations taken from Molina et al.<sup>4</sup>

*Photolysis Quantum Yield and Product Studies:* Rudolph and Inn<sup>5</sup> measured the CO quantum yield following the photolysis of OCS at 220, 225.8, 230, 253.7 nm (Hg lines) and 214 nm (Zn line). The CO quantum yield was found to be independent of the photolysis wavelength, within the precision of the measurement, with an average value of  $0.72 \pm 0.08$ . In a more direct CO quantum yield study, Zhao et al.<sup>7</sup> reported a CO quantum yield of  $>0.95$  at 248 nm. A unity CO quantum yield is recommended over the wavelength range 220–254 nm.

**I7. SF<sub>6</sub> (sulfur hexafluoride)**[Back to Index](#)

(Recommendation: 90-1, Note: 10-6, Evaluated: 10-6)

**Absorption Cross Sections:** Sulfur hexafluoride, SF<sub>6</sub>, has weak absorption at wavelengths >130 nm and its atmospheric photolysis occurs primarily at Lyman- $\alpha$  (121.567 nm). The absorption cross section at Lyman- $\alpha$  has been reported by Ravishankara et al.<sup>3</sup> Bertrand et al.,<sup>1</sup> Hitchcock and Van der Weil<sup>2</sup> and Zetzsch<sup>4</sup> have reported cross sections near Lyman- $\alpha$  that are within a factor of two of the Ravishankara et al. value. The recommended Lyman- $\alpha$  cross section of  $1.76 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$  is taken from Ravishankara et al.<sup>3</sup>

**Photolysis Quantum Yield and Product Studies:** No recommendation.

## I8. SF<sub>5</sub>CF<sub>3</sub> (trifluoromethyl sulfur pentafluoride)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* Trifluoromethyl sulfur pentafluoride, SF<sub>5</sub>CF<sub>3</sub>, does not absorb significantly at wavelengths >160 nm. The VUV absorption cross sections have been measured in several studies,<sup>1-5</sup> and photodissociation at Lyman- $\alpha$  (121.6 nm) accounts for the majority of the SF<sub>5</sub>CF<sub>3</sub> atmospheric photolysis rate. Chim et al.<sup>1</sup> reported  $\sigma(121.6 \text{ nm}) = 1.3 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ . The absorption cross sections reported by Takahashi et al.<sup>5</sup> and Limão-Vieira et al.<sup>3,4</sup> are significantly smaller, but agree to within 20% with each other. An average of the Takahashi et al. and Limão-Vieira et al. cross section values,  $7.1 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ , is recommended.

*Photolysis Quantum Yield and Product Studies:* No recommendation.

## I9. SO<sub>2</sub>F<sub>2</sub> (sulfuryl fluoride)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV and VUV absorption spectrum of sulfuryl fluoride, SO<sub>2</sub>F<sub>2</sub>, has been measured at room temperature by Pradayrol et al.<sup>2</sup> over the wavelength range 120–210 nm and by Papadimitriou et al.<sup>1</sup> at 184.9, 193, and 213.9 nm, Table 4I-5. The agreement between these two studies is ~10% at 184.9 nm, but large deviations exist at longer wavelengths. Due to the large discrepancy between these studies at wavelengths >185 nm no cross section recommendation is given.

*Photolysis Quantum Yield and Product Studies:* Papadimitriou et al.<sup>1</sup> reported the photodissociation quantum yield of SO<sub>2</sub>F<sub>2</sub> at 193 nm to be <0.02. This upper limit is recommended for wavelengths >193 nm. No photolysis product studies are currently available.

**Table 4I-5. Absorption Cross Sections of SO<sub>2</sub>F<sub>2</sub> at 298 K**

$\lambda$ (nm)	$10^{20} \sigma$ (cm <sup>2</sup> )
184.9	0.717
193	0.40
213.9	0.0208

## SECTION 4J. METAL PHOTOCHEMISTRY

### J1. NaOH (sodium hydroxide)

[Back to Index](#)

NaOH + hν	→ Na( <sup>2</sup> S) + OH	345.6 kJ mol <sup>-1</sup>	346 nm	(1)
	→ NaO + H	518.8 kJ mol <sup>-1</sup>	230 nm	(2)
	→ Na( <sup>2</sup> P) + OH	548.1 kJ mol <sup>-1</sup>	218 nm	(3)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The spectrum of NaOH, sodium hydroxide, has been reported by Rowland and Makide<sup>2</sup> (200–400 nm) and Self and Plane<sup>3</sup> (193–395 nm). Rowland and Makide inferred absorption cross section values and the average solar photodissociation rate from the flame measurements of Daidoji.<sup>1</sup> Self and Plane<sup>3</sup> used laser photofragment spectroscopy to measure absorption cross sections at 200 and 300 K from the production of Na atoms. The reported cross sections at the lower temperature are systematically smaller at all wavelengths, but fall within the limits of the measurement precision for the room temperature values. The results from the Rowland and Makide<sup>2</sup> and Self and Plane<sup>3</sup> studies are in reasonable agreement. The recommended cross sections in Table 4J-1 are taken from Self and Plane.<sup>3</sup>

*Photolysis Quantum Yield and Product Studies:* The quantum yield for photodissociation at wavelengths <346 nm is expected to be unity.

**Table 4J-1. Recommended Absorption Cross Sections of NaOH at 298 K**

λ (nm)	10 <sup>20</sup> σ (cm <sup>2</sup> )
193.4	551
205.7	867
205.9	563
210.3	185
216.3	489
218.7	696
225.2	1430
230.6	1820
234.0	1680
248.4	173
254.8	115
265.9	48
268.3	41.8
277.0	19.1
285.0	7.1
291.8	43.8
313.0	585
319.6	510
353.4	53.9
354.6	57
359.8	41.4

**J2. NaCl (sodium chloride)**[Back to Index](#)410 kJ mol<sup>-1</sup>

292 nm

(1)

(Recommendation: 87-41; Note: 10-6; Evaluated: 10-6)

*Absorption Cross Sections:* There are several studies of the UV absorption spectra of NaCl, sodium chloride, vapor. For a review of work prior to 1982, which was carried out at high temperatures, see Rowland and Rogers.<sup>2</sup> The study of Davidovitz and Brodhead<sup>1</sup> is particularly noteworthy. They report a NaCl absorption spectrum over the wavelength range 200–300 nm for temperatures between 1123–1223 K with a cross section of  $(3.5 \pm 0.3) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$  at 238 nm. The recommended cross sections in Table 4J-2 are taken from the work of Silver et al.,<sup>3</sup> who measured a spectrum of gas-phase NaCl at room temperature over the wavelength range 189–360 nm by directly monitoring Na atoms produced in the photolysis of NaCl.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for NaCl is expected to be unity for absorption above the dissociation threshold.

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of NaO, sodium oxide, has been reported by Self and Plane<sup>1</sup> at 200 and 300 K at wavelengths between 193 and 423 nm. Absorption cross sections were determined using pulsed laser photolysis of NaO combined with detection of Na atoms using laser induced fluorescence. A systematic decrease in absorption cross section at lower temperature was reported for all

wavelengths included in their study. The recommended absorption cross sections in Table 4J-3 are taken from Self and Plane,<sup>1</sup> which is the only study available.

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for NaO is expected to be unity for absorption above the dissociation threshold.

#### J4. NaO<sub>2</sub> (sodium superoxide)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

*Absorption Cross Sections:* The UV absorption spectrum of NaO<sub>2</sub>, sodium superoxide, has been reported by Rajasekhar et al.<sup>1</sup> at 193, 248, and 308 nm (230 K) and Self and Plane<sup>2</sup> at wavelengths between 193 and 423 nm (200, 230, and 300 K). Absorption cross sections were determined using pulsed laser photolysis of NaO<sub>2</sub> combined with detection of Na atoms using laser induced fluorescence. The results from these studies are in good agreement. At most wavelengths, the temperature dependence of the NaO<sub>2</sub> absorption cross sections falls within the estimated measurement uncertainty. The recommended absorption cross sections in Table 4J-4 are taken from Self and Plane.<sup>2</sup>

*Photolysis Quantum Yield and Product Studies:* The photolysis quantum yield for NaO<sub>2</sub> is expected to be unity for absorption above the dissociation threshold.

## 5.1 Introduction

Historically this section has presented evaluated and tabulated published information on stratospheric heterogeneous processes. However, in recent evaluations, its scope has been expanded to include tropospheric processes, initially due to community interest in tropospheric processes that affect the fluxes of reactive species into the stratosphere, as well as heterogeneous contrail and cloud processing of exhaust species from aircraft. In addition, to support NASA's expanded interest in the climate impact of tropospheric heterogeneous processes that influence greenhouse gas concentrations and the formation and chemical evolution of tropospheric fine aerosol particles, we have included kinetic data for selected heterogeneous interactions relevant to modeling cloud droplet and aqueous aerosol chemistry in the free troposphere. For instance, recent evaluations have built on reviews<sup>1,2</sup> of relevant inorganic and volatile organic species (VOCs) uptake on water ice surfaces relevant to aircraft contrails and cirrus clouds.

It should be noted, however, that both stratospheric and tropospheric heterogeneous chemistry are relatively new and evolving fields, and future results can be expected to change our quantitative and even our qualitative understanding on a regular basis. Their complexity is compounded by the difficulty of characterizing the chemical and physical properties of atmospheric heterogeneous surfaces and then reproducing suitable simulations in the laboratory.<sup>3,4</sup>

In this evaluation, selected uptake processes occurring on alumina, liquid water, water ice, solid salt, and salt solutions have been added or updated. The compilation of Henry's law parameters for pure water has been extended to include a large number of additional oxygenated organic, halo-organic, organic amine, and organic sulfide compounds. The compilation of Henry's law parameters in sulfuric acid solutions have also been expanded/updated for a few oxygenated organic species. A new compilation of Henry's Law constants for uptake into seawater (or into NaCl solutions at about 35‰ salinity) has been added, with a particular emphasis on halogenated organics.

## 5.2 Surface Types—Acid/Water, Liquids and Solids

To a first approximation there are three major types of water containing surfaces believed to be present at significant levels in the stratosphere. They are: (1) Type I polar stratospheric clouds (PSCs), nominally composed of nitric acid trihydrate (NAT,  $\text{HNO}_3 \cdot 3\text{H}_2\text{O}$ ); (2) crystals of relatively pure water ice, designated as Type II PSCs because they form at lower temperatures than Type I and are believed to be nucleated by Type I (similar surfaces may form as contrails behind high-altitude aircraft under some stratospheric conditions); and (3) sulfuric acid aerosol, which is nominally a liquid phase surface generally composed of 60–80 weight percent  $\text{H}_2\text{SO}_4$  and, concomitantly, 40–20 weight percent  $\text{H}_2\text{O}$ . While PSCs, as their name suggests, are formed primarily in the cold winter stratosphere at high latitudes, sulfuric acid aerosol is present year round at all latitudes and may influence stratospheric chemistry on a global basis, particularly after large injections of volcanic sulfur episodically increase their abundance and surface area. There is also evidence that ternary  $\text{H}_2\text{SO}_4/\text{HNO}_3/\text{H}_2\text{O}$  liquid solutions may play a significant role in PSC formation.

In addition to the major stratospheric surface types noted above, several other types of heterogeneous surfaces are found in the stratosphere and may play a significant role in some stratospheric processes. For instance, laboratory work has indicated that nitric acid dihydrate (NAD) may play an important role in the nucleation of Type I PSCs (Worsnop et al.,<sup>7</sup> Fox et al.<sup>1</sup>) and that mixtures of solid nitric acid hydrates and sulfuric acid tetrahydrate (SAT) (Molina et al.,<sup>4</sup> Zhang et al.<sup>8</sup>) and/or a more complex sulfuric acid/nitric acid hydrate (Fox et al.<sup>1</sup>) may also be key to understanding Type I PSC nucleation and evolution. Analyses of the range of atmospheric conditions possible in the polar stratosphere have also led to interest in solid SAT surfaces and possibly other forms of frozen sulfuric acid aerosols (Toon et al.,<sup>5</sup> Middlebrook et al.<sup>3</sup>), as well as liquid sulfuric

acid aerosols significantly more dilute than the 60–80 weight percent normally present at lower latitudes (Wolff and Mulvaney,<sup>6</sup> Hofmann and Oltmans,<sup>2</sup> Toon et al.<sup>5</sup>).

In the free troposphere the heterogeneous surfaces of interest include liquid or solid water (cloud droplets and crystals, contrails), and sulfate particles. Uptake data are compiled for liquid water for several reasons. First this surface is one asymptote of the aqueous acid aerosol continuum; second, the interactions of some trace species with liquid water and water ice (Type II PSC) surfaces are often similar, and third, the uptake of some trace species by liquid water surfaces in the troposphere can play a key role in understanding their tropospheric chemical lifetimes and thus, the fraction that may be transported into the stratosphere. The nature of the sulfate-bearing aerosol is complex. Field measurements by single-particle mass spectrometry show that the particles contain organic species to some degree. The chemical nature of the organics has not been quantified, although it is likely that they are highly oxidized having had long residence times in the atmosphere. Similarly, the inorganic composition is not clear. Most particles of continental origin are neutralized with ammonium, and there is some evidence from the free troposphere that this remains true far above the ground. However, in regions away from ammonia sources, there is the potential for the aerosol to be acidic. The phase of the particles may be either solid, or supercooled liquid. Low relative humidities and full neutralization with ammonia promotes crystallization, whereas higher relative humidities and acidic content are more frequently associated with liquid particles. The phase of the organics is not known but is unlikely to be crystalline and more likely to be an amorphous liquid or solid.

Phys. Chem.* **1993**, 97, 8541-8548.

### 5.3 Surface Types—Soot and Alumina

Aircraft at cruise altitudes and rocket exhausts contribute small but measurable amounts of carbonaceous “soot” (Pueschel et al.<sup>14</sup>) and aluminalized solid propellant rocket exhausts and spacecraft debris produce increasing levels of alumina (Al<sub>2</sub>O<sub>3</sub>) and similar metal oxide particles (Zolensky et al.<sup>17</sup>) in the stratosphere and upper troposphere. Soot lofted above from surface combustion sources may also be present in the upper troposphere, and to a lesser extent in the lower stratosphere. Alumina from rocket exhausts is generally emitted as liquid droplets from the rocket nozzle and crystalizes as the alpha or metastable gamma phases as it solidifies in the exhaust plume. “Soot” refers to a material that is a combination of elemental and organic carbon, with proportions varying depending on the source material and the combustion conditions. In studies of soot directed to understanding the interaction with atmospheric gases, two types of soot have been used: carbon blacks having relatively small hydrogen and oxygen contents (e.g. Degussa FW2, Cabot Monarch 1000, ground charcoal and spark-generated soot) and organic combustion soots having higher hydrogen, oxygen and nitrogen content (e.g. soot from the combustion of n-hexane, methane, propane, decane, ethylene, acetylene, toluene and stearic candles). In the case of organic combustion soot, even different fuels used to generate the soot have been reported to affect the chemistry; for example, the yields of HONO from the reaction of NO<sub>2</sub> with acetylene, toluene, ethylene and decane soot were observed to vary with the fuel used.<sup>4,10</sup>

Polycyclic aromatic hydrocarbons (PAH) and oxygenated polycyclic aromatic compounds (O-PAC) are major constituents of soot formed from the combustion of liquid fuels.<sup>1-3,5,9,11,15</sup> The bulk composition of soot can have varying amounts of C, H, and O. For example, Chughtai et al.<sup>6</sup> report that the composition (in weight %) of *n*-hexane soot varies from 87 to 92 % C, 1.2 to 1.6 % H, and 11 to 6% oxygen. Stadler and Rossi<sup>16</sup> showed that the elemental composition of the soot as well as its surface area depended on whether the flame was rich or lean; in the case of the rich flame giving a grey-colored soot, the composition (weight %) was 97.3% C, 0.83% H, 1.65% O, and 0.20% N while the lean flame produced a black soot comprised of 96.4% C, 0.19% H, 3.2% O, and 0.27% N.

The functional groups on the soot surface are expected to be important in terms of the uptake and reaction of gases on the surface. X-ray photoelectron spectroscopy (XPS) studies of *n*-hexane soot show surface carbon and oxygen, although the specific nature of the bonding could not be determined (Akhter et al.<sup>3</sup>). The surface functional groups on soot vary, depending on the fuel composition, method of generation and the post-treatment of the soot. For example, Degussa FW2 carbon black, which has been used in a number of studies of uptake and reactions of gases on soot, is post-treated with NO<sub>2</sub> by the manufacturer and Cabot Monarch 1000 is post-treated with aqueous HNO<sub>3</sub>. There may be sufficient NO and NO<sub>2</sub> concentrations generated under some conditions during the formation of soot by spark generators that these may also have been reacted with these gases prior to collection and uptake studies. Studies of a number of gases interacting with soot surfaces suggest there are at least two and likely more, types of reactive surface sites; one type reacts very rapidly, e.g. with O<sub>3</sub>, while others react more slowly. The first type may be most relevant to the reactions of soot particles in exhaust plumes from combustion sources, while the latter is most relevant to soot diluted in air.

Fourier transform infrared (FTIR), Raman and electron paramagnetic resonance (EPR) spectroscopic studies of *n*-hexane soot show C–O functionalities assigned to anhydrides and aryl ethers, alkyl ketones; they also detected -C=C–H, highly substituted aromatics and conjugated carbonyl-aromatic groups.<sup>2,15</sup> Kirchner et al.<sup>13</sup> measured the FTIR spectra of soot from the combustion of diesel fuel and *n*-hexane (described as “flame deposited”) and soot collected from a commercial spark generator in Ar, and from the emissions of a diesel automobile as well as Degussa FW2 soot (described as “filter deposited”). In all cases, absorption peaks characteristic of --C–C--, -C=C--, -C–O, aromatic -C=O, and carboxylic -C=O groups (both aromatic and aliphatic) were observed. However, the flame-deposited soot showed bands due to substituted aromatics while the filter-collected samples did not. The filter-deposited samples had bands due to aliphatic -C–H groups that were not observed for the flame-deposited soot. Only the spark-generated soot showed bands due to both -C=C–H and to -O–H.

For soot formed from the combustion of liquid fuels, the location in the flame at which the soot is collected also changes the surface enough to alter its reactions. For example, Akhter et al.<sup>2</sup> showed that the functional groups as well as particle size depend on the height of collection of soot from the base of the flame. Such changes appear to also alter the reactions of soot; for example, Gerecke et al.<sup>10</sup> measured HONO and NO yields from the reaction of NO<sub>2</sub> with ethylene soot and found that the HONO yield decreased with distance from the bottom of the flame that the soot was collected from, while the yield of NO increased. Kirchner et al.<sup>13</sup> reported much stronger infrared absorption bands due to substituted aromatics in soot samples collected from the combustion of *n*-hexane near the bottom of the flame compared to the top; in addition, absorption bands due to the -O–H group were only observed in samples collected at the bottom of the flame.

Not only can the surface groups directly affect its interaction with gases, but they determine the hygroscopic properties of the soot surface. Chughtai et al.<sup>7,8</sup> have shown that the hydration of soot surfaces depends on the fuel composition (particularly sulfur and trace metal content) and combustion conditions, as well as the extent of surface oxidation. A highly hygroscopic surface holding significant amounts of water may behave differently than a “dry” surface with respect to the interaction with gases; for example, black carbon suspended in aqueous solutions with ozone and irradiated to generate OH has been shown to help assist in the initiation of bulk solution phase OH chemistry.<sup>12</sup> There are also free radical sites on soot surfaces whose EPR signals are strongly affected by the adsorption of paramagnetic species such as NO<sub>2</sub> (e.g. see Chughtai et al.<sup>6</sup>). These unpaired electrons in soot may contribute to the surface reactivity.

The International Steering Committee for Black Carbon Reference Materials (<http://www.du.edu/~dwsmith/bcsteer.html>) has issued preliminary recommendations for representative black carbon reference materials. They recommend that soot formed from the combustion of saturated hydrocarbons, preferably *n*-hexane, be used for soot black carbon. For aerosol black carbon, they recommend the use of Urban Dust Reference Material (SRM) 1649a, which is a sample collected in Washington, D.C. in a baghouse in 1976–

1977. However, for studies of the uptake and reactions of gases in the atmosphere with combustion-generated soots, organic combustion generated soots, particularly *n*-hexane soot, appear to be the most reasonable surrogate.

## 5.4 Surface Types—Solid Alkali Halide Salts and Aqueous Salt Solutions

Some modeling studies also suggest that certain types of major volcanic eruptions transport significant levels of sodium chloride and associated alkali halide salts into the stratosphere (Michelangeli et al.<sup>2</sup>), so studies of stratospheric trace species interacting with solid NaCl or similar alkali halide salts, as well as salt solutions, have also been included. Sea salt aerosols are, of course, much more abundant in the troposphere, and have their largest influence on the chemistry of the marine boundary layer.

The heterogeneous chemistry of salt surfaces is very complex. For example; the uptake and reaction of gases with NaCl and NaBr have been shown to be very sensitive to the presence of small amounts of strongly adsorbed water (SAW) on the salt surface. Because water is not taken up on the 100 crystal surface of NaCl at room temperature, the SAW is thought to be concentrated at steps and edges where one water molecule can interact with two ions, resulting in a larger enthalpy of adsorption. This means that powders of salt, which have a larger surface-to-volume than single crystals, also have more SAW because of the relatively larger numbers of steps and edges. In addition, the amount of SAW on sprayed films is affected by the solvent used, with more SAW when water is used as the solvent. This SAW plays a key role in facilitating the reorganization of the

surface during the reaction; thus, it appears to mobilize the product ions and allow them to recrystallize into 3-D microcrystallites of product on the surface, exposing fresh salt and allowing the reaction to continue well beyond the point that the surface would normally passivate. While the overall features of this process are reasonably well understood, the exact nature of the SAW and the molecular level interactions and processes are not. The overall effect, however, is time-dependent trace gas uptake coefficients.

Salt particles may also exist as aqueous solutions, if the relative humidities are sufficiently high. Chemistry may then occur both on the surface of the liquid droplets and in the bulk. The surface composition is not necessarily the same as the bulk. In particular, it is believed that the more polarizable anions (such as bromide and iodide) partition to the surface of such particles, perhaps affecting their reactivity. When salt aerosols freeze, the resulting particle will be composed of ice and the vast majority of the solutes will be excluded into a brine that will exist on the surface of the particles and at any grain boundaries and crystal-crystal interfaces that exist. At sufficiently low temperatures, the sodium chloride component will crystallize but other components, such as bromide, are expected to remain in an increasingly concentrated brine.<sup>1</sup> It is also likely that marine organics are mixed with sea-salt inorganics, via the bubble bursting mechanism occurring at the sea surface when an organic microlayer exists on the sea surface. These organics may affect the surface reactivity of salt particles.

## 5.5 Surface Composition and Morphology

The detailed composition and morphology of each surface type are uncertain and probably subject to a significant range of natural variability. Certain chemical and physical properties of these surfaces, such as their ability to absorb and/or solvate HCl and HNO<sub>3</sub>, are known to be strongly dependent on their detailed chemical composition. Moreover, most heterogeneous processes studied under laboratory conditions (and in some cases proceeding under atmospheric conditions) can change the chemical composition of the surface in ways that significantly affect the kinetic or thermodynamic processes of interest. Thus, a careful analysis of the time-dependent nature of the active surface is required in the evaluation of measured uptake kinetics experiments. Experimental techniques which allow the measurement of mass accommodation or surface reaction kinetics with high time resolution and/or with low trace gas fluxes are often more credible in establishing that measured kinetic parameters are not seriously compromised by surface saturation or changing surface chemical composition.

The relevant kinetic uptake parameters: mass accommodation coefficients and surface reaction probabilities, are separately documented for relevant atmospheric trace gas species for the major and, where available, the minor stratospheric and upper tropospheric surfaces noted above. Since these parameters can vary significantly with surface composition (e.g., the H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O ratio for sulfate aerosol or the HNO<sub>3</sub>/H<sub>2</sub>O ratio for Type I PSC) the dependence of these parameters on surface composition is reviewed where sufficient data are available. In addition, in the notes to Table 5.1, we summarize the thermodynamic information that is now available to describe the non-reactive partitioning of species to a variety of surfaces, especially ice. Due to its chemical and morphological complexity, uptake values for soot are documented in a separate table.

## 5.6 Surface Porosity

The experimental techniques utilized to measure mass accommodation, heterogeneous reaction, and other uptake coefficients generally require knowledge of the surface area under study. For solid surfaces, and most particularly for water and acid ice surfaces formed *in situ*, the determination of how the molecular scale ice surface differs from the geometrical surface of the supporting substrate is not easy. Keyser, Leu, and coworkers have investigated the structure of water and nitric acid ice films prepared under conditions similar to those used in their flow reactor for uptake studies.<sup>6,7,9</sup> They have demonstrated that ice films grown *in situ* from the vapor can have a considerably larger available surface than that represented by the geometry of the substrate; they have also developed a simple model to attempt to correct measured uptake rates for this effect.<sup>8,9</sup> This model predicts that correction factors are largest for small uptake coefficients and thick films. The application of the model to experimental uptake data remains controversial (Keyser et al.,<sup>8</sup> Hanson and Ravishankara,<sup>4</sup> Kolb et al.<sup>10</sup>). Some experimenters prefer to attempt growing ice surfaces as smooth as possible and to demonstrate that their measured uptake coefficients are only weakly dependent on surface thickness (Hanson and Ravishankara<sup>5</sup>). For the case of

ice surfaces, it has been demonstrated that freezing thin films of liquid water leads to ice films that are smooth at the molecular level.<sup>1</sup>

Similar issues arise for uptake experiments performed on powdered, fused and single crystal salt or oxide surfaces (Fenter et al.,<sup>2</sup> Hanning-Lee et al.<sup>3</sup>). There are two issues here. First, the molecular level Brunauer, Emmett, Teller (BET) surface area that is commonly measured by determining the mass of a gas such as N<sub>2</sub> adsorbed by a given sample mass is, for many atmospheric solids, larger than the geometric surface area. However, determining the BET surface area of porous materials does not necessarily reflect the available surface area for molecules larger than that used in the BET measurement. Second, many experimental studies have used samples consisting of multiple layers of particles in order to increase the amount of gas that is taken up and hence improve the accuracy of the measurement. However, there is considerable uncertainty in how to accurately assess the fraction of the total sample that is available for reaction. When recommendations are made for uptake coefficients on solid alkali salts in this assessment, the values have generally been obtained using at least two different sample types (e.g., powders, single crystals and spray-deposited films) and/or two different techniques (e.g., flow tubes and Knudsen cells).
