The issue of surface area available for uptake is also important for interpreting uptake measurements on soot and soot surrogate surfaces. The degree to which measured uptake parameters must be corrected for porosity effects will remain in some doubt until a method is devised for accurately determining the effective surface area for the surfaces actually used in uptake studies.

Some studies evaluated in this review assume that the effective ice or salt surface area is the geometrical area, but more recent studies on solid surfaces generally attempt to assess the available surface area by employing BET measurements and porosity models. However, uncertainty in true reactive surface area for heterogeneous uptake on solids is often the dominate systematic error in reporting uptake coefficient values for these systems and makes evaluation of these data across laboratories and techniques difficult.

## 5.7 Temperature Dependences of Parameters

A number of laboratory studies have shown that mass accommodation coefficients and, to some extent, surface reaction probabilities can be temperature dependent. While these dependencies have not been characterized for many systems of interest, temperature effects on kinetic data are noted where available. More work that fully separates heterogeneous kinetic temperature effects from temperature controlled surface composition is obviously needed.

## 5.8 Solubility Limitations

The uptake of certain trace gases by atmospherically relevant surfaces is often governed by solubility limitations rather than kinetic processes. In these cases properly analyzed data can yield measurements of trace gas solubility parameters relevant to stratospheric conditions. In general, such parameters can be strongly dependent on both condensed phase composition and temperature. Such parameters may be very important in stratospheric models, since they can govern the availability of a reactant for a bimolecular heterogeneous process (e.g., the concentration of HCl available for the HCl + ClONO<sub>2</sub> reaction on sulfuric acid aerosols) or the gas/condensed phase partitioning of a heterogeneous reaction product (e.g., the HNO<sub>3</sub> formed by the reaction of N<sub>2</sub>O<sub>5</sub> on sulfuric acid aerosols). Surface saturation limitations have also been observed in experimental uptake studies on solid surfaces, including liquid water and water/acid ice surfaces.

## 5.9 Data Organization

Data for trace-gas heterogeneous interactions with relevant condensed-phase surfaces are tabulated in Tables 5-1 through 5-7. These are organized into:

- Table 5-1—Mass Accommodation Coefficients and Reversible Uptake Data for Surfaces Other than Soot
- Table 5-2—Surface Reaction Probabilities ( $\gamma$ ) for Surfaces Other Than Soot
- Table 5-3—Soot-Surface Uptake Coefficients
- Table 5-4—Solubility Data for Pure Water
- Table 5-5—Ion Specific Schumpe Parameters
- Table 5-6—Solubility Data for Acids
- Table 5-7—Solubility Data for Sea Water

## 5.10 Parameter Definitions

Mass accommodation coefficients ( $\alpha$ ), represent the probability of reversible uptake of a gaseous species colliding with the condensed surface of interest. For liquid surfaces this process is associated with interfacial (gas-to-liquid) transport and is generally followed by bulk liquid phase solvation. Examples include: simple surface absorption, absorption followed by ionic dissociation and solvation (e.g., HCl + nH<sub>2</sub>O  $\leftrightarrow$  H<sup>+</sup>(aq) + Cl<sup>-</sup>(aq)), and absorption followed by a reversible chemical reaction with a condensed phase substituent (e.g., SO<sub>2</sub> + H<sub>2</sub>O  $\leftrightarrow$  H<sup>+</sup> + HSO<sub>3</sub><sup>-</sup> or CH<sub>2</sub>O + H<sub>2</sub>O  $\leftrightarrow$  CH<sub>2</sub>(OH)<sub>2</sub>).

The term “sticking coefficient” is often used for mass accommodation on solid surfaces where physisorption or chemisorption takes the place of true interfacial mass transport.

Processes involving liquid surfaces are subject to Henry’s law, which limits the fractional uptake of a gas phase species into a liquid. The distribution of a substance between the gas and liquid phase is controlled, at equilibrium, by the Henry’s Law constant for that substance, which relates the concentration of the substance in solution to the partial pressure of the substance in the gas phase. In these tables, we present the Henry’s Law constants as solubility values:

$$H = [\text{solution}]/P(\text{gas})$$

The units are molar (M) for solution concentration and atmosphere (atm) for the partial pressure in the gas phase. In many studies and other compilations, volatility values are presented, which are the inverse of solubility values. Often, other concentration units are used, sometimes the same unit for both phases. This leads to a dimensionless value, with no indication from the units if it pertains to solubility or to volatility.

Henry’s Law is a limiting law, strictly valid only at the limit of zero concentration. For most gasses at concentrations of interest, deviations from this law are not significant. The value of the Henry’s Law constant,  $H$ , depends strongly upon temperature. For a typical gas, it decreases with increasing temperature at lower temperatures, at least down to 0°C. At higher temperatures, typically well above 298 K, the value will increase with temperature. Over limited temperature ranges, the value is well represented by a linear relationship between the logarithm of  $H$  and the reciprocal of temperature:

$$\ln(H) = A + B/T$$

For a number of gasses, the experimental data are sufficient to display the expected curvature in a plot of  $\ln H$  vs.  $1/T$ . In this review, we have represented these results by the three-parameter equation:

$$\ln(H) = A + B/T + C \ln(T)$$

Below 0°C, measurements in strong acid solutions have suggested that the Henry's Law constant for a substrate would continue to increase as the temperature is lowered. A study on the solubility of benzene, alkyl benzenes, and methyl and ethyl *tert*-butyl ethers, however, indicate that this is not the case.<sup>11</sup> In this study, the values were found to decrease with temperature in supercooled water. Indeed, the results from 25°C to -25°C are almost symmetrical around 0°C. Additional studies on this phenomenon are clearly needed, particularly for smaller solutes.

If the gas phase species is simply solvated, a physical Henry's law constraint holds; if the gas phase species reacts with a condensed phase substituent, as in the sulfur dioxide or formaldehyde hydrolysis cases noted above, a "chemically modified" or "effective" Henry's law constraint holds (Clegg and Brimblecombe,<sup>1</sup> Schwartz,<sup>9</sup> Watson et al.<sup>12</sup>). This value will typically involve an equilibrium constant for the chemical process, along with the physical Henry's law constant.

The solubility of a gas also depends upon the presence of other substances in the solution. The best known effect is that of an added salt. In most cases, the addition of a salt to the solution results in a lowering of the solubility of the gas. This effect is usually described by the Sechenov equation:

$$\log(c^0/c) = \log(H^0/H) = K_S c_s$$

which relates the ratio of the concentrations of gas dissolved for a given pressure in the absence,  $c^0$ , and presence,  $c$ , of a given concentration of salt,  $c_s$ . The proportionality constant is the Sechenov coefficient,  $K_S$ . The Sechenov coefficient is specific to both the gas and the specific salt. Thus, in general, one needs a new value for any particular gas-salt combination, a tremendous amount of data. For this reason, models have been developed to extend measurements of  $K_S$  to systems for which no measurements have been made. Schumpe and co-workers<sup>8,13</sup> developed the particular procedure adopted in this review. It assumes that  $K_S$  is composed of ion- and gas-specific constants:

$$K_S = \sum (h_i + h_G) n_i$$

where  $h_i$  is the ion-specific constant,  $h_G$  is the gas-specific constant, and  $n_i$  is the ion index. For a mixed electrolyte solution,

$$\log(H^0/H) = \sum (h_i + h_G) c_i$$

The small temperature dependence of  $K_S$  is assumed to lie completely in  $h_G$ . Thus,

$$h_G = h_{G,0} + h_T (T - 298.15 \text{ K})$$

Weisenberger and Schumpe<sup>13</sup> analyzed 892 Sechenov constants for various gases in salt solutions over the temperature range 273 K to 363 K. They derived an optimum set of  $h_i$ ,  $h_{G,0}$ , and  $h_T$  parameters for a diverse set of ions and gases. Values for O<sub>2</sub> and H<sup>+</sup> were set to zero to make the set unique. The standard deviation in the predicted Sechenov constants is 0.026. We have included their values for the ion-specific parameters in Table 5-5.

Available gas-specific constants,  $h_{G,0}$  and  $h_T$ , are included in Table 5-4, along with the Henry's law constants for pure water. In Table 5-4, we present those "salting out" parameters included in the optimum set derived by Weisenberger and Schumpe, along with some parameters derived from other studies. In the latter cases, the ion parameters are considered fixed and we solve for the gas-specific parameters.

Available Henry's law parameters for sulfuric acid/water, and in a few cases, sulfuric acid/nitric acid/water solutions are presented in Table 5-6. Effective Henry's law constants are designated  $H^*$ , while simple physical Henry's law constants are represented by  $H$ . Effective Henry's law constants are also employed to represent decreased trace gas solubilities in moderate ionic strength acid solutions via a Sechenov coefficient formulation which relates  $H^*$  to the concentration of the acid.<sup>4</sup> Available Henry's law constants for reactive upper tropospheric/stratospheric species in binary sulfuric acid/water solutions, and for a few cases of ternary sulfuric acid/nitric acid/water solutions, are tabulated as a function of acid weight percent and temperature. It is presently unclear whether "surface solubility" effects govern the uptake on nominally solid water ice or HNO<sub>3</sub>/H<sub>2</sub>O ice surfaces in a manner analogous to bulk solubility effects for liquid substrates and no solubility parameters for these "ice" systems are presented; the reader is referred to the ice uptake studies in Table 5.1.

In Table 5-7, Henry's Law parameters are presented for uptake into seawater, or into water with a salinity of 35‰. The major focus is on halogenated organic compounds, due to the possibility that this could have an impact on their atmospheric lifetimes. Due to the limited temperature ranges of these studies, only a two-parameter fit was utilized.

For some trace species on some surfaces, experimental data suggest that mass accommodation coefficients untainted by experimental saturation limitations have been obtained. These are tabulated in Table 5-1. In other cases experimental data can be shown to be subject to Henry's law constraints, and Henry's law constants, or at least their upper limits, can be determined. Some experimental data sets are insufficient to determine if measured "uptake" coefficients are true mass accommodation coefficients or if the measurement values are lower limits compromised by saturation effects. These are currently tabulated, with suitable caveats, in Table 5-1.

Also included in the specific notes in Table 5-1 are parameters relating to the non-reactive uptake of gases to solid atmospheric surfaces, such as ice. These quantities are useful for determining the likelihood that gas-phase species will be scavenged to the condensed phase, and to interpret the rates of surface-phase reactions. Many experimental approaches that can measure reactive uptake or mass accommodation coefficients can also assess the degree of non-reactive uptake, so these data are reported in the same Table. Experimental studies usually measure a total uptake (i.e. molecules or moles of adsorbate per unit surface area) at a specific temperature and gas-phase partial pressure or concentration.

By varying the gas-phase amounts, an adsorption isotherm is measured. For surfaces such as ice, simple isotherms such as the Langmuir form have been utilized. While this isotherm neglects adsorbate-adsorbate interactions and assumes that all adsorption sites are equivalent, these may be reasonable assumptions for ice surfaces, which are highly dynamic and where adsorbate molecules are likely to be strongly hydrated. From the isotherm, the saturated surface coverage at high gas-phase concentrations and the gas-surface partition coefficient can be assessed:

$$\theta \equiv \text{fractional surface coverage} = K_{\text{conc}} [\text{gas}] / (1 + K_{\text{conc}} [\text{gas}]) = K_p P_{\text{gas}} / (1 + K_p P_{\text{gas}})$$

where  $K_{\text{conc}}$  and  $K_p$  are the adsorption coefficients, depending on whether concentration or pressure units are used for the gas phase. For consistency with the rest of the evaluation and to match the approach typically used in the literature, surface uptakes will be reported in units of molecules/cm<sup>2</sup>. Correspondingly, adsorption coefficients will be converted into  $K_{\text{conc}}$  units, i.e. cm<sup>3</sup> molecules<sup>-1</sup>. Note that a partitioning coefficient ( $K_{\text{part}}$ , units molecules cm<sup>-2</sup> / molecules cm<sup>-3</sup>) can also be derived by taking the slope of a plot of uptake to gas-phase concentration in the surface-unsaturated regime. The relationship between a  $K_{\text{conc}}$  value derived from a Langmuir adsorption isotherm to a partition coefficient ( $K_{\text{part}}$ ) is:

$$K_{\text{part}} = K_{\text{conc}} N_{\text{sat}}$$

where  $N_{\text{sat}}$  is the saturated surface coverage in units of molecules cm<sup>-2</sup>.

By varying the temperature in uptake studies, the heat of adsorption can be derived in a van't Hoff analysis from the temperature dependence of the partition or adsorption coefficients. This approach is most accurate at low surface coverages where adsorbate-adsorbate interactions are likely to be fewest. While we report such values from the literature, care should be taken in their interpretation because an assumption of this approach is that the surface structure and the strength of the adsorbate-surface interactions remain constant as a function of temperature. Also, as the temperature changes, the degree of adsorbate-adsorbate interactions may change as well. Surface reaction probabilities ( $\gamma$ ) are kinetic values for generally irreversible reactive uptake of trace gas species on condensed surfaces. The rates of such processes may not be limited by Henry's law constraints; however, the fate of the uptake reaction products may be subject to saturation limitations. For example, N<sub>2</sub>O<sub>5</sub> has been shown to react with sulfuric acid aerosol surfaces. However, if the H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O ratio is too high, the product HNO<sub>3</sub> will be insoluble, and a large fraction will be expelled back into the gas phase. Surface reaction probabilities for substantially irreversible processes are presented in Table 5-2. Reaction products are identified where known.

Surface reaction probabilities on crystalline and non-ice amorphous solid surfaces, such as alumina and alkali salts are particularly susceptible to surface saturation effects, especially when exposed to the relatively high trace gas concentrations sometimes employed in laboratory experiments. In the case of gaseous HNO<sub>3</sub> reacting with NaCl for example, there is a rapid initial uptake of HNO<sub>3</sub> and formation of nitrate on the surface, followed by a decrease to a relatively constant (but slowly declining) value. When they are available, we tabulate the initial uptake coefficient,  $\gamma_0$ , in Table 5-2, since that value often sets the upper limit for atmospheric uptake. In the

corresponding note we may also site the reactive uptake coefficient appropriate to longer time exposure when the uptake appears to have reached an approximate steady-state,  $\gamma_{ss}$ .

The total experimental uptake coefficient measured in laboratory heterogeneous kinetic experiments are also often represented by the symbol  $\gamma$ . In those cases where surface and/or bulk reaction dominate the uptake, the total uptake coefficient ( $\gamma_{total}$ ) and reactive uptake coefficient ( $\gamma_{rxn}$ ) may well be identical. More formally, for cases where bulk liquid phase reaction is facile and there are no gas phase diffusion constraints, the total uptake coefficient for aerosol or cloud droplets can be approximated in terms of  $\gamma_{rxn}$  and  $\gamma_{sol}$  as:<sup>6</sup>

$$\frac{1}{\gamma_{total}} = \frac{1}{\alpha} + \frac{1}{\gamma_{sol} + \gamma_{rxn}}$$

where

$$\gamma_{sol} = \frac{8HRT}{\pi^{1/2}\bar{c}} \left(\frac{D}{t}\right)^{1/2}$$

and

$$\gamma_{rxn} = \frac{4HRT}{\bar{c}} (Dk_{rxn})^{1/2}$$

where t is the time integrated exposure of the trace gas to the liquid surface, R is the gas constant, D is the liquid phase diffusion coefficient, and  $\bar{c}$  is the mean trace gas molecular speed. In the limit of low solubility or long exposure time  $\gamma_{sol}$  becomes negligible and

$$\frac{1}{\gamma_{total}} = \frac{1}{\alpha} + \frac{1}{\gamma_{rxn}}$$

Discussion of how to use this approach to model chemical reactions in liquid stratospheric aerosols can be found in Hanson et al.<sup>2</sup> and Kolb et al.<sup>6</sup> Note that these formulations are approximate. In cases where separate terms are competitive, more rigorous solution of the kinetic differential equations may be appropriate.

For solid surfaces, bulk diffusion is generally too slow to allow bulk solubility or bulk kinetic processes to dominate uptake. For solids, reactive uptake is driven by chemisorption/chemical reaction at the interface, a process that can also influence trace gas uptake on liquids. For liquids, surface reaction ( $\gamma_{surf}$ ) occurs in parallel, rather than in series with mass accommodation, thus:

$$\gamma_{total} = \gamma_{surf} + \left[ \frac{1}{\alpha} + \frac{1}{\gamma_{sol} + \gamma_{rxn}} \right]^{-1}$$

Examples where this more complex situation holds for liquid surfaces can be found in Hu et al.<sup>3</sup> and Jayne et al.<sup>5</sup> In such cases  $\gamma$  may be significantly larger than  $\alpha$ .

Uptake of gases on soot may occur due to three different processes: (1) physisorption (e.g. SO<sub>2</sub> or HNO<sub>3</sub> at room temperature and low nitric acid pressures); (2) reaction with the surface (e.g. NO<sub>2</sub>), and (3) catalytic decomposition/reactions of the gas on the surface. All three processes may occur in parallel, and the relative contributions of each of these three may vary during the course of the reaction as the surface “ages.” As discussed above, there are different types of reactive sites on soot, leading in some cases to a rapid initial uptake followed by a slower uptake; these are often characterized as reactions on “fresh” and “aged” surfaces respectively. Another complexity is that in some cases the geometric surface areas were used to calculate the uptake coefficients from the experimental data while in others, the available reactive surface area was estimated and used.

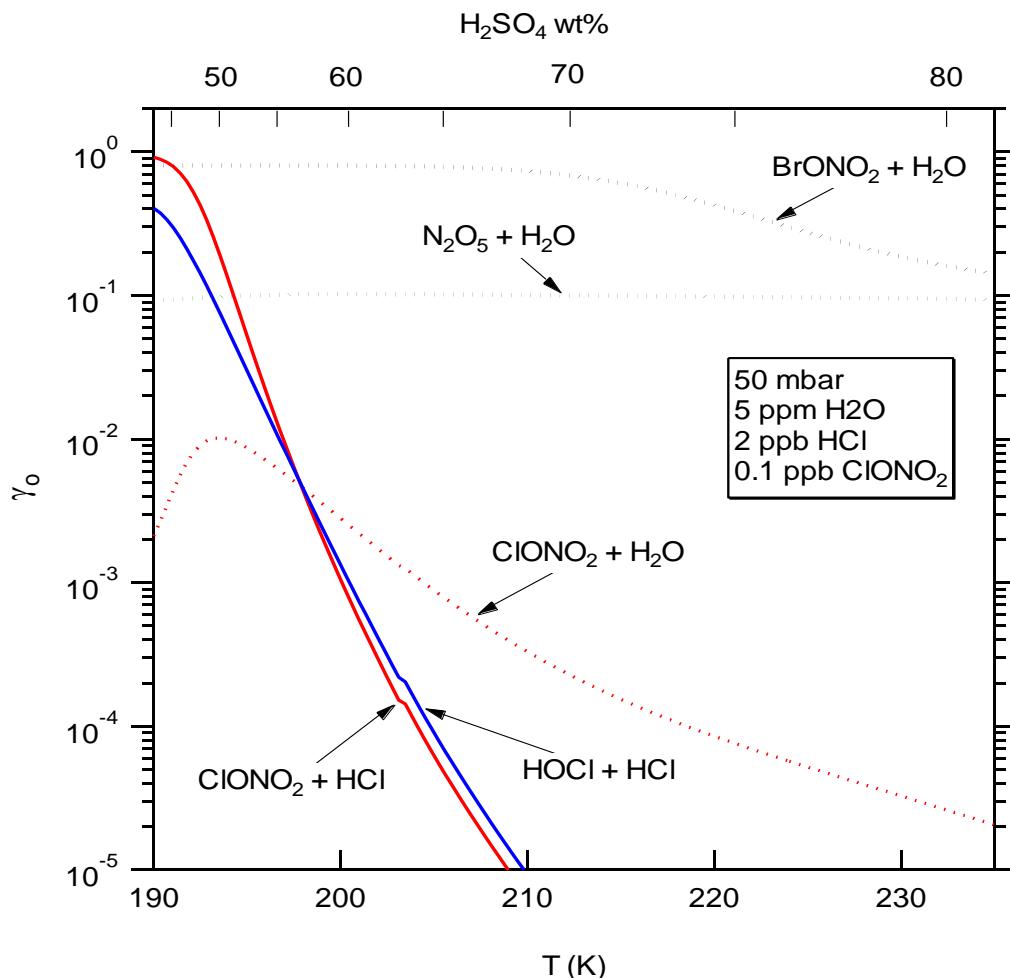

Because of these complexities with soot heterogeneous chemistry, uptake coefficients for soot interactions with gases have been broken out into a separate Table 5-3 rather than being included with the other surfaces in Tables 5-1 and 5-2. When the uncertainty is more than an order of magnitude, a recommendation is not given in Table 5-3 and the range of reported values is given in the Notes. In most cases, the available reactive surface area rather than the geometric areas have been used in obtaining the uptake coefficients; in those cases where the geometric area was used but a higher available surface area was involved in the measured uptake, the uptake coefficient is given as an upper limit. Data are most commonly available for room temperature or there are very limited data at lower temperatures characteristic of the upper troposphere.

The data in Tables 5-1 and 5-2 for uptake on non-soot surfaces are organized by trace gas species, since some systematic variation may be expected for surface accommodation or reaction as the surface composition and/or phase is varied. Data presented for one surface may be judged for “reasonableness” by comparing with data for a “similar” surface. In some cases it is not yet clear if surface uptake is truly reversible (accommodation) or irreversibly reactive in nature. In such cases the available uptake coefficients are generally tabulated in Table 5-1 as mass accommodation coefficients, a judgment that will be subject to change if more definitive data become available.

Where a specific evaluated value for an accommodation coefficient or reaction probability has been obtained, an estimated uncertainty factor is also tabulated. However, when the data evaluation yielded only a lower or upper limit, no uncertainty factor can be reliably estimated and none is presented.

Description of and reference citations to many of the laboratory techniques used to obtain the data in the following tables can be found in Kolb et al.<sup>6</sup> Reactions of N<sub>2</sub>O<sub>5</sub>, ClONO<sub>2</sub>, HOCl and BrONO<sub>2</sub> on/in sulfuric acid are generally dependent on the species' Henry's law solubility and liquid phase diffusion coefficient in the liquid acid as well as the surface and/or liquid phase reaction rate parameters. All of these processes are generally functions of the acid composition and temperature (Hanson et al.,<sup>2</sup> Robinson et al.,<sup>7</sup> Shi et al.<sup>10</sup>). Thus, these reactions' reactive uptake coefficients must be represented by a complex phenomenological or empirical models that defy simple entry into Table 5-2. The notes in Table 5-2 for these reactions discuss and present the models adopted.

To aid in visualizing the resulting reactive uptake parameters the results for several reactions have been plotted in Figure 5.1 as a function of temperature for a background pressure of 50 mbar and background water vapor and HCl mixing ratios of 5 ppmv and 2 ppbv, respectively. These calculations are presented for monodisperse background sulfate aerosol particles with a radius of  $1 \times 10^{-5}$  cm (0.1  $\mu\text{m}$ ).

**Figure 5-1.** Recommended reactive uptake coefficients as a function of temperature for key stratospheric heterogeneous processes on sulfuric acid aerosols. For CIONO<sub>2</sub> and HOCl species, the aerosol radius used in the calculation is 10<sup>-5</sup> cm, a typical value in the stratosphere. Because the current uptake models for N<sub>2</sub>O<sub>5</sub> and BrONO<sub>2</sub> hydrolysis do not provide the information about the reacto-diffusive length ( $\ell$ ), the aerosol radius used in the calculation is assumed to be much larger than their reacto-diffusive length (i.e.  $\ell$  for N<sub>2</sub>O<sub>5</sub> and BrONO<sub>2</sub> are set to zero.)

‡ May be affected by surface saturation

## 5.12 Notes to Table 5-1

1. **O on H<sub>2</sub>O(s).** Murray and Plane<sup>1</sup> measured the uptake of O atoms on water ice at temperatures relevant to the upper mesosphere (112–151 K), where noctilucent clouds are present. Their results indicate that in the absence of oxygen molecules the uptake coefficient  $\alpha$  is small ( $7 \times 10^{-6}$ ). They recommend the following expression:  $\alpha = 7 \times 10^{-6} + 1.5 \times 10^{-10} \exp(11.4 \text{ kJ/mol}/RT)$ , with an uncertainty of  $\pm 24\%$ .

2. **O on H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** Knudsen cell experiment of Baldwin and Golden<sup>1</sup> measured an uptake coefficient limit of  $<10^{-6}$ , this result probably cannot be equated with an accommodation coefficient due to surface saturation.

3. **O<sub>3</sub> on H<sub>2</sub>O(s) and HNO<sub>3</sub>•nH<sub>2</sub>O.** Undoped ice surfaces saturate too quickly for reliable measurements. When ice is doped with Na<sub>2</sub>SO<sub>3</sub> to chemically remove absorbed O<sub>3</sub> the apparent  $\alpha$  increases to  $1 \times 10^{-2}$  (0.1 M) or up to  $4 \times 10^{-2}$  (1 M) (Dlugokenky and Ravishankara<sup>1</sup>). Limit of  $\gamma < 10^{-6}$  for undoped ice is consistent with earlier measurement by Leu<sup>3</sup> of  $\geq 1 \times 10^{-4}$  and with  $< 6 \times 10^{-5}$  obtained by Kenner et al.<sup>2</sup> Dlugokenky and Ravishankara also measured the tabulated value of an uptake coefficient for O<sub>3</sub> on a NAT “like” surface, but the data were difficult to reproduce and the surfaces were not well characterized. Kenner et al. also measured a lower limit for an uptake coefficient of  $8 \times 10^{-5}$  on NAT at 183 K, but this measurement is also certainly limited by surface saturation.

4. **O<sub>3</sub> on H<sub>2</sub>O(l).** Utter et al.<sup>9</sup> used a wetted wall flow tube technique with various chemical scavengers to measure a lower limit for  $\alpha$  of  $2 \times 10^{-3}$ . The stopped flow measurement technique using an SO<sub>3</sub><sup>2-</sup> scavenger (Tang and Lee<sup>8</sup>) is subject to saturation effects, so their quoted  $\alpha$  of  $5.3 \times 10^{-4}$  is also taken as a lower limit. Using a droplet train flow reactor Hu et al.<sup>1</sup> measured a value of  $\sim 0.1$  at 277 K with I<sup>-</sup> as a reactive scavenger, consistent with a more extensive droplet train flow reactor measurement by Magi et al.<sup>2</sup> yielding a value of  $\geq 0.1$  also using I<sup>-</sup> as a reactive scavenger and with the aerosol flow tube work of Rouviere et al.<sup>5</sup> that also obtained a value of  $> 0.1$  at room temperature. Schurath et al.<sup>6</sup> used a coaxial flow liquid jet to obtain a value of  $4.5 \times 10^{-3}$  at 298 K, probably limited by surface saturation although they also used I<sup>-</sup> as a reactive scavenger. Müller and Heal<sup>3</sup> obtained a value of  $4 \times 10^{-2}$  at 293 K in a wetted wall flow tube with S<sub>2</sub>O<sub>3</sub><sup>2-</sup> as a reactive scavenger. Schütze and Herrmann<sup>7</sup> measured a lower limit of  $2 \times 10^{-2}$  at 298 K using a suspended droplet flow reactor method that also employed I<sup>-</sup> as a reactive scavenger. It is highly likely that the mass accommodation coefficient for ozone on liquid water is  $\geq 0.01$  between  $\sim 275$  and 300 K and may be significantly higher, although it is possible that interfacial reactions with near surface I<sup>-</sup> bias some mass accommodation evaluations high because surface reactive uptake occurs in parallel with mass accommodation. Molecular dynamic simulations of O<sub>3</sub> uptake on water by Roeselová et al.<sup>4</sup> indicate a mass accommodation coefficient of order 0.1.

- 5.  $\text{O}_3$  on  $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$ .** Flow tube measurements (Dlugokencky and Ravishankara<sup>2</sup>) of an uptake coefficient limit of  $<10^{-6}$  on both 50 and 97 wt%  $\text{H}_2\text{SO}_4$  surfaces are consistent with earlier, but probably less quantitative, static systems measurements of Olszyna et al.<sup>5</sup> and aerosol chamber measurements of Harker and Ho,<sup>3</sup> who report uptake coefficients of the order  $10^{-8}$  or less for a variety of sulfuric acid concentrations and temperatures. In these earlier experiments, doping the  $\text{H}_2\text{SO}_4$  with  $\text{Ni}^{2+}$ ,  $\text{Cr}^{2+}$ ,  $\text{Al}^{3+}$ ,  $\text{Fe}^{3+}$ , and  $\text{NH}_4^+$  (Olszyna et al.<sup>5</sup>) or  $\text{Al}_2\text{O}_3$  or  $\text{Fe}_2\text{O}_3$  (Harker and Ho<sup>3</sup>) did not significantly increase measured  $\text{O}_3$  loss. An upper limit of  $1 \times 10^{-6}$  was also reported by Baldwin and Golden<sup>1</sup> for 97 wt%  $\text{H}_2\text{SO}_4$  at 295 K. Il'in et al.<sup>4</sup> performed static tube reactor measurements on 98 wt.% sulfuric acid at 239, 258, 273 K measuring uptake coefficients between 1.2 and  $1.75 \times 10^{-6}$ . Although these measurements are slightly larger than the limits in the other studies, uptake values this small are extremely hard to quantify and these measurements are not seen to be in serious disagreement with other studies finding slightly lower upper limits. All measurements are subject to solubility limitations and probably do not reflect true limits on mass accommodation.

- 6.  $\text{OH}$  on  $\text{H}_2\text{O(s)}$ .** Cooper and Abbatt<sup>1</sup> analyzed uptake rates in a wall-coated flow tube to determine an initial  $\gamma \sim 0.1$  over the temperature range of 205–230 K. Uptake coefficients decreased at longer exposure times, indicating surface saturation. These data indicate that  $\alpha$  is at least 0.1 and possibly much larger. This is confirmed by an earlier experiment using a coated insert/flow tube technique by Gershenson et al.,<sup>2</sup> which yielded  $\alpha > 0.4$  at 253 K.

**7. OH on H<sub>2</sub>O(l).** A lower limit of  $\alpha$  on pure water of  $3.5 \times 10^{-3}$  at 275 K was determined by Hanson et al.<sup>1</sup> using a liquid-wall flow tube. Takami et al.<sup>4</sup> using a gas/liquid impinging flow technique obtained a pure water value near pH 7 at 293 K of  $(4.2 \pm 2.8) \times 10^{-3}$  while values 2 to 3 times higher were obtained for acid (pH=1) and basic (pH=10–13) aqueous solutions; a value of  $(1.1 \pm 0.4) \times 10^{-2}$  was obtained when benzoic acid was added as a radical scavenger. Takami et al. also observed that uptake for pure water solutions decreased with gas/liquid contact times, indicating a saturation limitation and explaining the higher uptake values observed for solutions with H<sup>+</sup>, OH<sup>-</sup>, or benzoic acid reactive scavengers. Based on these experimental results a value of  $\alpha \geq 0.1$  is suggested. This recommendation is consistent with molecular dynamics calculations by Roeselová et al.<sup>2,3</sup> who first published simulation values at room temperature 0.2 to 0.3, but later reported a value of 0.83 at 300 K using revised intermolecular potentials.

**8. HO<sub>2</sub> on H<sub>2</sub>O(l), aqueous salt solutions and H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** Determination of  $\alpha$  in liquid-wall flow tube (Hanson et al.<sup>2</sup>) is dependent on gas-phase diffusion corrections; measured limit ( $\alpha > 0.02$ ) is consistent with  $\alpha = 1$ . In the aqueous salt aerosol measurements of Mozurkewich et al.,<sup>3</sup> HO<sub>2</sub> was chemically scavenged by Cu<sup>++</sup> from added CuSO<sub>4</sub> to avoid Henry's law constraints; the measured limit of  $> 0.2$  is also consistent with  $\alpha = 1$ . Thornton and Abbatt<sup>6</sup> and Taketani et al.<sup>4,5</sup> have raised the upper limit to the mass accommodation coefficient to  $> 0.4$  for Cu<sup>++</sup> doped aqueous particles composed of sulfuric acid, ammonium sulfate, sodium chloride and potassium chloride, for relative humidities between 35 and 75% at room temperature. George et al.<sup>1</sup> report a value of  $> 0.1$  for copper-doped salt solutions as measured at low HO<sub>2</sub> gas phase concentrations in an aerosol flow tube reactor. This is consistent with the mass accommodation coefficient inferred by prior studies.

**9. H<sub>2</sub>O on H<sub>2</sub>O(s).** Uptake coefficient measurements are available from Leu<sup>5</sup> (0.3 (+0.7, -0.1)) at 200 K, Haynes et al.<sup>4</sup> ( $1.06 \pm 0.1$  to  $0.65 \pm 0.08$  from 20 to 185 K), Brown et al.<sup>1</sup> ( $0.99 \pm 0.03$  between 85 and 150 K and  $0.97 \pm 0.10$  between 97 and 145 K), Fluckiger et al.<sup>3</sup> (0.43 at 200 K using D<sub>2</sub>O<sup>18</sup>), and Magee et al.<sup>6</sup> (0.006 at 223 K using levitated particles, in a wind tunnel). Uptake coefficients measured by Delval et al.<sup>2</sup> and Pratte et al.,<sup>8</sup> that should be viewed as lower limits to the mass accommodation coefficient, show a strong negative temperature dependence consistent with a precursor adsorption model; values are about 0.1

at 200 K. The sticking coefficient of D<sub>2</sub>O on ice at a translational energy of 69 kJ/mole has been measured under ultrahigh vacuum conditions to be close to unity, consistent with other measurements (Hundt et al.<sup>7</sup>). At higher temperatures, Skrotzki et al.<sup>9</sup> have measured the growth of ice particles formed by deposition nucleation from 190 to 235 K in a large, cooled cloud chamber where supersaturations are generated by pressure expansion. Ice crystal number density and size, and ice water content are monitored. By comparing microphysical models to measured ice properties, the mass accommodation coefficient has been inferred to be 0.7(+0.3/-0.5), independent of temperature and particle size indicating that there is not a significant kinetic barrier to the uptake of water over these temperatures. The lower value measured by Magee et al. at elevated temperatures is not consistent with this report.

- 10. H<sub>2</sub>O on H<sub>2</sub>O(I).** Because the uptake of water vapor on and evaporation of water from liquid water are fundamental processes that are linked by microscopic reversibility and play extremely important roles in cloud physics, they have been the subject of over 75 published experimental studies spanning over eight decades. Many of these studies were reviewed by Marek and Staub,<sup>7</sup> who note values of  $\alpha$  deduced from these experiments range from ~0.001 to 1.0, with experiments involving growing water drops tending to higher values. Recently published experiments support values near the higher end of the range. Shaw and Lamb<sup>8</sup> used an electrodynamic droplet levitation cell to make simultaneous ice nucleation/water droplet evaporation rate observations to deduce a range of  $0.04 < \alpha < 0.1$  at 237 K. Li et al.<sup>5</sup> used a droplet train flow reactor to measure the uptake of small excesses of H<sub>2</sub><sup>17</sup>O on water droplets that were in equilibrium with the surrounding normal water vapor, deducing a value of  $0.17 \pm 0.03$  at 280 K that increased to  $0.32 \pm 0.04$  at 258 K. Winkler et al.<sup>11</sup> used Mie scattering analyses of the growth of freshly nucleated droplets in an expansion chamber to deduce  $0.4 < \alpha < 1.0$  over a temperature range of 270 to 290 K and  $0.8 < \alpha < 1.0$  for 250–270 K. Voigtlander et al.<sup>10</sup> analyzed droplet growth in a laminar diffusion flow reactor to estimate  $0.3 < \alpha < 1.0$  at 275–277 K. Saykally, Cohen, and co-workers<sup>1,3,9</sup> performed a series of evaporation experiments from liquid jets and jet breakup droplet trains in very low-pressure reactors that approximate free evaporation conditions. Their studies of H/D isotope fraction in vapor from D<sub>2</sub>O doped water jets yielded estimates of  $\sim 0.15 < \alpha < \sim 0.3$  for the temperature range of 255–295 K.<sup>1</sup> Further experiments with jet break-up droplet trains produced an estimate of  $\alpha = 0.62 \pm 0.09$  for H<sub>2</sub>O between 245 and 298 K<sup>9</sup> and  $\alpha = 0.57 \pm 0.06$  for D<sub>2</sub>O between 255 and 295 K.<sup>3</sup> Maerefat and coworkers used a unique shock tube

method to study the time resolved evolution of water film thickness on a window surface to estimate that  $\alpha = 0.35$  over the temperature range 297.1–299.1 K.<sup>6</sup> Jakubczyk and co-workers applied an atmospheric pressure single droplet evaporation electrodynamic trap technique<sup>4,13,14</sup> and a continuum vapor diffusion and heat transfer model, which they argue is more complete than that employed by Winkler et al.<sup>12</sup> and Voigtlander et al.<sup>10</sup> When applied to temperature dependant data Jakubczyk and co-workers report  $\alpha = 0.13 \pm 0.01$  at 293.1 K increasing to  $0.18 \pm 0.05$  at 273.1 K,<sup>14</sup> in close agreement with magnitude and temperature dependence reported by Li et al.<sup>5</sup> Given the results from this wide range of experiments, it seems clear that mass accommodation values of water vapor on liquid water for temperatures below 295 K must exceed 0.1. The Li et al. and Winkler et al. experiments are further discussed in Davidovits et al.,<sup>2</sup> which notes that reasons for the differences in their deduced values are not yet understood.

- 14. H<sub>2</sub>O on NaCl(s).** Fenter et al.<sup>3</sup> used Knudsen cell/mass spectrometry methods to measure  $\gamma < 2 \times 10^{-4}$  for H<sub>2</sub>O(g) uptake on NaCl powders, an observation confirmed by Beichert and Finlayson-Pitts,<sup>1</sup> who found  $\gamma < 1 \times 10^{-5}$ . However, Dai et al.<sup>2</sup> used FTIR spectroscopy on NaCl crystallite films at 240 and 296 K to determine that a water adlayer does adhere to dry salt and that a small fraction of surface sites (<1%) cause H<sub>2</sub>O dissociation. It is likely that the measurements of Fenter et al. and Beichert and Finlayson-Pitts were affected by surface saturation.

- 16. H<sub>2</sub>O<sub>2</sub> on H<sub>2</sub>O(s).** The uptake of H<sub>2</sub>O<sub>2</sub> on ice surfaces has been studied by Clegg and Abbatt<sup>1</sup> who measured relatively small, reversible uptake between 213 and 238 K in a coated-wall flow tube experiment. The uptake scaled linearly with partial pressure and there was a weak temperature dependence, increasing with increasing temperature. By contrast, using the same flow tube technique but with a more direct H<sub>2</sub>O<sub>2</sub> detection technique, values reported by Crowley and co-workers<sup>2</sup> are several orders of magnitude higher. A value of  $K_{\text{part}} = 2.1 \times 10^{-5} \exp(3800/T)$  cm is reported. Although the source of discrepancy between

these studies is not clear, the later study by Crowley and co-workers is preferred by virtue of the more direct detection technique.

- 22.  $\text{NO}_3$  on  $\text{H}_2\text{O(l)}$ .** Rudich et al.<sup>2</sup> analyzed uptake on KI solutions as a function of  $[\text{I}^-]$  at 273 K. This work suggested that  $\alpha > 0.04$ , but this result may be biased due to reactive uptake by interfacial  $\text{I}^-$ . Potentially smaller estimates of  $\alpha$  were suggested by the work of Thomas et al. as quoted in Mihelcic et al.<sup>1</sup> at 293 K on pure water and Thomas et al.,<sup>4</sup> on 293 K 0.1 M NaCl solutions, which reported uptake coefficients of  $2.5 \times 10^{-3}$  and  $2 \times 10^{-3}$ , respectively. Schütze and Herrman<sup>3</sup> used a single suspended droplet flow reactor technique and the resistor model to analyze uptake data on aqueous Alizarin Red S dye and NaCl solutions to estimate a 293 K value of  $\alpha = 4.2 (+2.2, -1.7) \times 10^{-3}$ , consistent with the limits suggested by Thomas and co-workers. However, their data do not rule out possible surface reactions with either interfacial  $\text{Cl}^-$  or Alizarin Red S. A lower limit of  $2 \times 10^{-3}$  for 273–293 K is recommended.

- 23.  $\text{HONO}$  on  $\text{H}_2\text{O(s)}$ .** Fenter and Rossi<sup>3</sup> measured reversible uptake on water ice between 180 and 200 K using a Knudsen cell technique. An initial uptake coefficient of  $1 \times 10^{-3}$  suggests that  $\alpha$  equals or exceeds this value. Chu et al.<sup>2</sup> used a cylindrical flow reactor to measure the uptake coefficient as a function of temperature, obtaining values ranging from  $3.7 \times 10^{-3}$  at 178 K to  $6.4 \times 10^{-4}$  at 200 K, in good agreement with the results of Fenter and Rossi. On the other hand, Chu et al. report significantly lower values after correction for the effects of surface porosity, i.e.  $1.4 \times 10^{-4}$  at 178 K and  $1.3 \times 10^{-5}$  at 200 K (see Keyser et al.<sup>6</sup>). The adsorption enthalpy has been measured to be  $-32 \text{ kJ/mole}$  by Bartels-Rausch et al.<sup>1</sup> Using radioactively labeled HONO uptake on ice was studied in a packed ice bed between 213 and 253 K by Kerbrat et al.,<sup>5</sup> who attempted to disentangle surface adsorption and bulk diffusion. A partition coefficient to the ice surface is reported ( $K_{\text{Part}} = 7.4 \times 10^{-9} \exp(5.4 \times 10^3/T) \text{ cm}$ ) with an enthalpy of adsorption of  $-45 \pm 20 \text{ kJ/mole}$ . The kinetics of the diffusion into the bulk ice were studied. In another study from the same group, nitrous acid and acetic acid simultaneous uptake measurements to packed ice beds were found to be well described by a competitive Langmuir adsorption isotherm between 213 and 243 K. Labeled nitrous acid was monitored by radioactive methods, and acetic acid by CIMS (Kerbrat et al.<sup>4</sup>).

24. **HNO<sub>3</sub> on H<sub>2</sub>O(s).** Leu<sup>11</sup> report a lower limit of 0.2 at 195 K, Hanson<sup>5</sup> measured an uptake coefficient of greater than 0.3 at 191.5 and 200 K, and Aguzzi and Rossi<sup>2</sup> measured an uptake coefficient of 0.3 over the temperature range from 180 to 190 K with the value decreasing at T > 195 with an exponential temperature dependence of  $-(3400 \pm 500)/T$ . Aguzzi and Rossi attributed this change to an increasing evaporation rate, concluding that the accommodation coefficient most likely remains large. In a higher temperature regime, Hynes et al.<sup>8</sup> measured uptake coefficients as a function of temperature decreasing from 0.03 at 215 K to 0.006 at 235 K and Hudson et al.<sup>6</sup> report initial uptake coefficients ranging from 0.007 at 209 K to 0.003 at 220 K. On the other hand, Ullerstam et al.<sup>15</sup> report a temperature independent lower limit to the uptake coefficient of 0.1 from 200 K up to 239 K. It is unclear the extent to which the work of Aguzzi and Rossi, Hudson et al., and Hynes et al. are affected by outgassing of nitric acid from wall surfaces during uptake experiments at high temperatures, which would lead to apparently low uptake coefficients. Also, uptakes on surfaces that have already been exposed to nitric acid are smaller than on those that are freshly exposed. Additional uncertainty is introduced by the effective ice surface area in the older fast-flow measurements (see Keyser et al.<sup>9</sup>) but these effects should be absent in the work of Hynes et al. and Ullerstam et al., which used smooth ice surfaces.

For low partial pressure experiments and temperatures above about 190 K, the uptake of nitric acid displays both reversible and irreversible components in amounts that do not exceed monolayer coverage.<sup>1,15,16</sup> For high partial pressures and/or low temperatures, a different uptake regime is encountered where much larger uptakes can occur that are not necessarily atmospherically relevant. In particular, the ice surfaces may melt to form a thermodynamically stable nitric acid solution on the surface, or nitric acid hydrate layers may form. Focusing only on the sub-monolayer, atmospherically-relevant uptake regime, it is believed that the uptake proceeds initially via adsorption to the ice surface, with some degree of diffusion along grain boundaries and into the underlying ice bulk then proceeding. The relative fractions of adsorbed molecular nitric acid and dissociated nitric acid are not fully known, although it is likely that nitrate is present to a large degree.<sup>16</sup> Indeed, XPS and NEXAFS spectra of ice at 230 K which contains surface nitrate, formed from NO<sub>2</sub> hydrolysis, indicate that the nitrate is similar in character to that of ions present in a concentrated solution (Krepeleva et al.<sup>10</sup>). The implication is that the chemical environment on the surface of ice of adsorbed nitric acid is similar to that of pure ice and concentrated nitrate solutions. For initial exposures, uptakes are saturated at between 1 to  $3 \times 10^{14}$  molecules cm<sup>-2</sup><sup>1,7,15,16</sup> when the gas phase concentrations are high (roughly  $10^9$  to  $10^{10}$  molecules/cm<sup>3</sup>) for temperatures between roughly 200 and 230 K. At lower concentrations, the surface is unsaturated and the uptakes obey temperature-dependent Langmuir adsorption curves, with enhanced uptake at low temperatures.<sup>15</sup> In this regime, for temperatures between 214 to 239 K, the adsorption coefficient (converted to concentration units) for the initial uptake is  $K_{\text{conc}} = -8.2 \times 10^{-12} T + 2.01 \times 10^{-9}$  cm<sup>3</sup>/molecule. The temperature dependence is qualitatively consistent with observations of nitric acid uptake to cirrus cloud particles, with more uptake at low temperature.<sup>15</sup> For repeated exposures, the amounts of nitric acid decrease relative to the initial uptake value. Cox et al.<sup>4</sup> have used a numerical model of the Ullerstam et al.<sup>15</sup> data to decouple adsorptive uptake from uptake arising by nitric acid diffusing into the upper layers of the ice. As a result, an effective temperature-dependent adsorption equilibrium constant has been deduced, which shows that roughly 85% of the uptake measured by Ullerstam et al. is adsorptive. The related enthalpy of adsorption is -31 kJ/mole. Using a radioactive tracer, chromatographic technique Bartels-Rausch et al.<sup>3</sup> have measured the adsorption enthalpy to be -44 kJ/mole, and Hynes et al.<sup>7</sup> report a value of -54 kJ/mole from a Van't Hoff analysis.

Note that uptake may be affected by co-adsorbed species. Studies by Hynes et al.<sup>7</sup> and Sokolov and Abbatt<sup>12</sup> involving co-adsorption of HCl indicate that HNO<sub>3</sub> binds more strongly than HCl, but that the presence of HCl does lead to suppressed HNO<sub>3</sub> uptake relative to behavior on bare ice surfaces. Also, enhanced uptake is observed if the ice surfaces are growing and not at equilibrium,<sup>14</sup> probably arising through the formation of a metastable solution of HNO<sub>3</sub> in ice. The uptakes are larger under burial conditions than the amounts of nitric acid that are thermodynamically stable.<sup>13</sup>

- 27. HNO<sub>3</sub> on HNO<sub>3</sub>•nH<sub>2</sub>O(I).** Rudolf and Wagner<sup>1</sup> used an aerosol expansion chamber techniques to deduce that  $\alpha$  for HNO<sub>3</sub> on 278 K H<sub>2</sub>O/HNO<sub>3</sub> droplets is  $>0.3$  and probably close to 1. The consistency of this value with smaller ( $\sim 0.2$ ) values measured for uptake on pure water by Van Doren et al.<sup>2</sup> is unclear, since the mechanism of co-condensation is unknown and the composition of the surface in the aerosol expansion chamber experiments may be kinetically controlled and has not been well determined.

- 28. HNO<sub>3</sub> on H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O and H<sub>2</sub>SO<sub>4</sub>•4H<sub>2</sub>O(s).** Initial uptake at 73 wt% H<sub>2</sub>SO<sub>4</sub> allows a measurement of  $\alpha = 0.11 \pm 0.01$  at 283 K (Van Doren et al.<sup>7</sup>). This value is expected to increase at lower temperatures, in a manner similar to H<sub>2</sub>O(1) uptake (Van Doren et al.<sup>6</sup>). Total HNO<sub>3</sub> uptake is subject to Henry's law solubility constraints, even at stratospheric temperatures (Reihs et al.<sup>4</sup>). Solubility limitations also affected the earlier "sticking coefficient" measurements of Tolbert et al.<sup>5</sup> for 75 wt% H<sub>2</sub>SO<sub>4</sub> at 230 K. Hanson<sup>2</sup> measured an uptake coefficient of  $>0.3$  for frozen 57.7 wt% sulfuric acid at 191.5 and 200 K. Baldwin and Golden<sup>1</sup> reported a lower limit of  $2.4 \times 10^{-4}$  on 97 wt% H<sub>2</sub>SO<sub>4</sub> at 295 K, also reflecting solubility limits. Iraci et al.<sup>3</sup> monitored nitric acid trihydrate growth on sulfuric acid tetrahydrate with infrared techniques, measuring HNO<sub>3</sub> uptake coefficient limits of  $>0.03$  at 192.5 K and  $>0.08$  at 192 K. These measurements involved co-deposition of water vapor.

- 29. HO<sub>2</sub>NO<sub>2</sub> on H<sub>2</sub>O(s).** Li et al.<sup>1</sup> measured an uptake coefficient of  $0.15 \pm 0.10$  at 200 K, where the uptake may be limited by surface saturation and appears to be reversible with no decomposition. Consistent with this, adsorption of HOONO<sub>2</sub> to ice was studied in a coated wall flow tube using CIMS for gas phase detection (Ulrich et al.<sup>2</sup>) at temperatures between 230 and 253 K. Only reversible uptake was observed, with a partition coefficient,  $K_{\text{Part}}$ , of  $3.74 \times 10^{-12} \times \exp(7098/T)$  cm. Uptake is much smaller than for stronger acids, such as HNO<sub>3</sub>.

- 31. NH<sub>3</sub> on H<sub>2</sub>O(s).** NH<sub>3</sub> interacts somewhat efficiently with ice surfaces according to the coated-wall flow tube results of Jin and Chu<sup>1</sup> at 190 K. The porosity-corrected uptake coefficients are  $4 \times 10^{-4}$ , with no evidence for surface saturation when partial pressures of  $10^{-6}$  Torr are used over hours of exposure time. This suggests that the surface is being substantially modified by the NH<sub>3</sub> exposure.

- 32. NH<sub>3</sub> on H<sub>2</sub>O(l).** Ponche et al.<sup>3</sup> used a droplet train technique to obtain  $\alpha = (9.7 \pm 0.9) \times 10^{-2}$  at 290 K, and Bongartz et al.<sup>1</sup> used a liquid jet technique to obtain  $\alpha = 4.0 (+3.0, -0.05) \times 10^{-2}$  at the same temperature. These experiments were extended to other temperatures by Carstens et al.,<sup>2</sup> demonstrating a negative temperature dependence. Ammonia uptake on liquid water as a function of both pH and temperature was investigated by Shi et al.<sup>4</sup> using a droplet train apparatus, yielding values that also demonstrated negative temperature dependence, varying between 0.08 at 290 K to 0.35 at 260 K. The data from these four studies are all in reasonable agreement and a temperature dependent data plot with a non-linear least squares fit to all of these measurements has been published by Worsnop et al.<sup>6</sup> Earlier levitated droplet evaporation experiments<sup>5</sup> on NH<sub>4</sub>Cl obtained a larger evaporation coefficient of  $\alpha = 0.29 \pm 0.03$ , which is discounted because of the indirect nature of the experiment.

- 33. CO<sub>2</sub> on H<sub>2</sub>O(s).** The uptake of carbon dioxide on ice has been studied in a classical BET adsorption experiment from 209 to 263 K by Ocampo and Klinger.<sup>1</sup> The system is unusual in that the measured uptakes are higher at higher temperatures, unlike the behavior displayed by most gases that physically adsorb to ice surfaces. Similar to SO<sub>2</sub>, the uptake may occur via formation and decomposition of H<sub>2</sub>CO<sub>3</sub> in which case the ice surfaces may be somewhat acidified by this process.

- 34. CO<sub>2</sub> on H<sub>2</sub>O(l).** Noyes et al.<sup>2</sup> used a dynamic stirring technique to monitor pressure decreases in a closed cylinder. They inferred  $\alpha = (5.5 \pm 0.5) \times 10^{-8}$  at 293 K. This technique is uncalibrated against more widely used procedures and probably suffers from severe surface saturation effects. Schurath et al.<sup>3</sup> employed a coaxial jet flow technique to measure a 298 K value of  $\alpha$  of  $1-2 \times 10^{-4}$ , noting that its low Henry's law solubility in water made the measurement very difficult. For this reason the measurement probably also suffered from surface saturation even at their shortest gas/liquid contact times, so this value is most likely a lower limit. Boniface et al.<sup>1</sup> used a bubble train reactor to study the uptake by water as a

function of pH. At high pH the reaction of CO<sub>2</sub> with OH<sup>-</sup> partially relieves surface saturation allowing determination that the uptake coefficient, and therefore  $\alpha$ , is  $\geq 1 \times 10^{-5}$ , consistent with the value measured by Schurath et al. and completely inconsistent with the much lower value obtained by Noyes et al.<sup>2</sup>

- 38.  $\text{CH}_3\text{CH}_2\text{OH}$  on  $\text{H}_2\text{O(l)}$ .** Jayne et al.<sup>1</sup> measured uptake from 260–291 K with a droplet train flow reactor and derived mass accommodation coefficients fitting  $\alpha/(1-\alpha) = \exp(-\Delta G_{\text{obs}}^{\ddagger}/RT)$ , where  $\Delta G_{\text{obs}}^{\ddagger} = -11.0 \text{ kcal/mol} + 46.2 \text{ cal mol}^{-1} \text{ K}^{-1} \text{ T(K)}$ . Similar, but somewhat larger values were reported for chloro-, bromo-, and iodo-ethanols. Shi et al.<sup>3</sup> used the same technique to measure the uptake of both normal and deuterated ethanol over the temperature range of 263–291 K as a function of pH. Normal ethanol uptake was not dependent on pH, while the uptake of the deuterated species was enhanced by surface isotopic exchange, especially at high and low pH. The mass accommodation values obtained for normal ethanol obtained by Shi et al. ranged from  $0.128 \pm 0.023$  at 263 K to  $0.057 \pm 0.005$  are consistent, within experimental error, with the lowest temperature value measured by Jayne et al., but are significantly higher above ~275 K. Katrib et al.<sup>2</sup> also used the droplet train technique to measure the ethanol mass accommodation coefficient between ~266 and 281 K, obtaining lower values than those measured by Shi et al.,<sup>3</sup> but agreeing with the higher temperature data of Jayne et al.<sup>1</sup> Katrib et al. obtained mass accommodation coefficients fitting  $\alpha/(1-\alpha) = \exp(-\Delta G_{\text{obs}}^{\ddagger}/RT)$ , where  $\Delta G_{\text{obs}}^{\ddagger} = -(5.6 \pm 1.5) \text{ kcal/mol} + (27.4 \pm 5.5) \text{ cal mol}^{-1} \text{ K}^{-1} \text{ T(K)}$ . While the data of Shi et al. and Katrib et al. are off-set by about a factor of three, the negative temperature dependencies measure by the two groups are very similar. The differences among the three data sets are difficult to explain, given that all three used essentially the experimental same technique; the recommended lower limit is consistent with the lower values measured by Katrib et al.<sup>2</sup>

- 44. CH<sub>2</sub>O on H<sub>2</sub>O(s).** The uptake of formaldehyde on ice in a coated-wall flow tube has been measured by Winkler et al.<sup>2</sup> They report reversible uptake behavior with a partition coefficient of  $K_{\text{part}} = 0.7 \text{ cm}$ , temperature independent between 198 and 208 K. At much higher temperatures (238 to 268 K), the partitioning to ice was studied by Burkhardt et al.<sup>1</sup> using artificial snow. It was found that the partitioning increased at lower temperatures, in accord with Winkler et al. Although there is also likely to be a significant surface component, the partition coefficients in this work are expressed in bulk solubility format, ranging from 56 to 245 M/atm from 268 to 238 K.

- 45. CH<sub>2</sub>O on H<sub>2</sub>O(l) and H<sub>2</sub>SO<sub>4</sub>•mHNO<sub>3</sub>•nH<sub>2</sub>O(l).** Jayne et al.<sup>4</sup> report uptake measurements for 0–85 wt% H<sub>2</sub>SO<sub>4</sub> and 0–54 wt% HNO<sub>3</sub> over a temperature range of 241–300 K. Measured uptake coefficients vary from 0.0027–0.027, increasing with H<sup>+</sup> activity (Jayne et al.<sup>4</sup> and Tolbert et al.<sup>5</sup>), and with increasing pH above 7 (Jayne et al.<sup>3</sup>). Reversible uptake is solubility limited through reactions to form H<sub>2</sub>C(OH)<sub>2</sub> and CH<sub>3</sub>O<sup>+</sup>. A model of uptake kinetics (Jayne et al.<sup>4</sup>) is consistent with  $\gamma = 0.04 \pm 0.01$  for all compositions. A chemisorbed surface complex dominates uptake at 10–20 wt% H<sub>2</sub>SO<sub>4</sub>, and CH<sub>3</sub>O<sup>+</sup> formation dominates above 20 wt% (Tolbert et al.,<sup>5</sup> Jayne et al.,<sup>4</sup> and Iraci and Tolbert<sup>2</sup>). Low temperature (197–214 K) uptake studies by Iraci and Tolbert<sup>2</sup> confirm that uptake is solubility limited for uptake coefficients in the 10<sup>-3</sup> to 10<sup>-2</sup> range even at low temperatures. These chemical mechanisms allow  $\gamma$  to greatly exceed  $\alpha$  for strong acidic and basic solutions. A full uptake model for acid solutions is presented in Jayne et al.,<sup>4</sup> and for basic solutions in Jayne et al.<sup>3</sup> XPS surface analysis by Fairbrother and Somorjai<sup>1</sup> failed to see CH<sub>3</sub>O<sup>+</sup> surface species reported by Jayne et al.; however, their sensitivity of 1% of surface coverage is too poor to see the predicted amounts of the surface species.

- 46. CH<sub>3</sub>CHO on H<sub>2</sub>O(s).** The uptake of acetaldehyde to ice surfaces was measured in a Knudsen cell from 120 to 160 K by Hudson et al.<sup>1</sup> finding the uptake to decrease with increasing temperature. Fitting the results to a Langmuir adsorption model and extrapolating to 210 K, the authors conclude that there will be low surface coverages under upper tropospheric conditions of  $<5 \times 10^9$  molecules/cm<sup>2</sup>. Hudson et al. report the initial uptake coefficient and find it to be strongly temperature dependent, decreasing with increasing temperature to less than 0.01 at 160 K. Petitjean et al.<sup>2</sup> have used a coated-wall flow tube to measure relatively small reversible uptakes. They report saturated surface coverages of between 1 and  $2 \times 10^{14}$  molecules/cm<sup>2</sup> and a heat of adsorption of -16 kJ/mole from 203 to 233 K. A higher heat of adsorption is calculated if the entropy of adsorption is fixed according to Trouton's rule. Larger uptakes are observed on mixed ice and nitric acid solution surfaces.

- 49. CH<sub>3</sub>C(O)CH<sub>3</sub> on H<sub>2</sub>O(s).** The uptake of acetone to ice surfaces has been measured in both coated-wall flow tubes<sup>1,2,4-6</sup> and in a Knudsen cell.<sup>3</sup> Reversible uptake that is described by the simple Langmuir adsorption isotherm is demonstrated. Winkler et al. report a partition coefficient  $K_{\text{part}} = 1.25 \times 10^{-10} \exp(5575/T)$  cm, an enthalpy of adsorption of -46 kJ/mole, and a saturated surface coverage of  $3 \times 10^{14}$  molecules/cm<sup>2</sup>, for temperatures between 198 and 218 K. Symington et al.<sup>5</sup> report a partition coefficient  $K_{\text{part}} = 3.04 \times 10^{-9} \exp(4625/T)$  cm, an enthalpy of adsorption of -39 kJ/mole, and a saturated surface coverage of  $3 \times 10^{14}$  molecules/cm<sup>2</sup>, for temperatures between 208 and 228 K. Between 193 to 223 K, Peybernes et al.<sup>4</sup> report an adsorption enthalpy of -49 kJ/mole with a smaller saturated surface coverage of  $1.3 \times 10^{14}$  molecules/cm<sup>2</sup>. By fitting observed adsorption and desorption profiles at 190 to 220 K, Behr et al. conclude that a two-site model best represents their observations. Total adsorbed species are close to  $3 \times 10^{14}$  molecules/cm<sup>2</sup> at saturation but the modeling suggests the presence of two crystallographic surfaces, one which binds acetone more strongly than the other. The relative proportion of the sites changes with ice film age, and adsorption energies are between -32 and -49 kJ/mole. Bartels-Rausch et al. report very similar adsorption enthalpies ( $-51 \pm 2$  kJ/mole) on a range of ice surfaces, including single and polycrystalline laboratory crystal ice, and snow from the field, at 198 to 223 K. Hudson et al. report somewhat smaller adsorption enthalpies at low temperatures (140 to 170 K) ranging from -28 to -39

kJ/mole. They also measure the initial uptake coefficient and find it to be strongly temperature dependent, decreasing with increasing temperature to less than 0.1 at 170 K.

- 56. CH<sub>3</sub>C(O)OH on H<sub>2</sub>O(s).** The uptake of acetic acid on ice has been measured in coated-wall flow tubes by Sokolov and Abbatt<sup>3</sup> from 222 to 245 K, by Picaud et al.<sup>2</sup> from 193 to 223 K, by von Hessberg et al.<sup>5</sup> from 197 to 227 K, and Symington et al.<sup>4</sup> from 208 to 238 K. In all cases, either BET or Langmuir adsorption isotherms are demonstrated and saturated surface coverage is observed with between  $2$  to  $3 \times 10^{14} \text{ molecules/cm}^2$ . The values of the partition coefficients between the Sokolov and Abbatt, von Hessberg et al. and Symington et al. studies agree to within roughly a factor of two, whereas the Picaud et al. results are one to two orders of magnitude smaller at low temperatures. The overall adsorption coefficient expressions from the Sokolov and Abbatt data, von Hessberg et al. and Symington et al. are  $K_{\text{conc}} = 8.3 \times 10^{-28} \exp(7825/T)$ ,  $6.55 \times 10^{-25} \exp(6610/T)$ , and  $2.2 \times 10^{-23} \exp(5703/T) \text{ cm}^3/\text{molecule}$  (assuming a saturated surface coverage of  $2.5 \times 10^{14} \text{ molecules/cm}^2$ ), respectively. Nitrous acid and acetic acid simultaneous uptake measurements to packed ice beds were found to be well described by a competitive Langmuir adsorption isotherm between 213 and 243 K. Labeled nitrous acid was monitored by radioactive methods, and acetic acid by CIMS (Kebrat et al.<sup>1</sup>).

- 57. CH<sub>3</sub>C(O)OH on H<sub>2</sub>O(l).** Jayne et al.<sup>1</sup> using a droplet train flow reactor measured uptake coefficients for acetic acid between 260 and 291 K and derived a mass accommodation coefficient fitting  $\alpha/(1-\alpha) = \exp(-\Delta G_{\text{obs}}^{\ddagger}/RT)$ , where  $\Delta G_{\text{obs}}^{\ddagger} = -8.1 \text{ kcal mol}^{-1} + 34.9 \text{ cal mol}^{-1} \text{ K}^{-1} T(\text{K})$ . Shi et al.<sup>2</sup> used the same technique to measure the uptake of both normal and deuterated acetic acid at 258 K and pH = 7. They obtained  $\alpha = 0.19 (\pm 0.03)$  for normal acetic acid, while the uptake coefficient of the deuterated species was enhanced by surface isotopic exchange, equaling 0.96 ( $\pm 0.21$ ).

- 61. HCl on H<sub>2</sub>O(s).** The uptake coefficients of Leu<sup>16</sup> (0.4; +0.6, -0.2) and Hanson and Ravishankara<sup>10</sup> ( $\geq 0.3$ ) are in reasonable agreement at stratospheric ice temperatures. At somewhat higher temperatures (205 K), Hynes et al.<sup>13</sup> measured slightly lower values (0.1) which decreased at higher temperatures. At very low temperatures (80 to 120 K), Rieley et al.<sup>21</sup> measured  $\alpha = 0.95 \pm 0.05$ .

A great deal of experimental effort (Abbatt et al.,<sup>1,2</sup> Barone et al.,<sup>3</sup> Koehler et al.,<sup>14</sup> Chu et al.,<sup>4</sup> Foster et al.,<sup>6</sup> Graham and Roberts,<sup>8</sup> Graham and Roberts,<sup>9</sup> Hanson and Ravishankara,<sup>10</sup> Henson et al.,<sup>11</sup> Hynes et al.,<sup>13</sup> Leu et al.,<sup>17</sup> Marti et al.,<sup>18</sup> McNeil et al.,<sup>20</sup> and McNeil et al.<sup>19</sup>) has gone into understanding the magnitude and nature of the uptake of HCl by ice surfaces under stratospheric and upper tropospheric conditions. A general observation is that water ice at stratospheric temperatures can take up a significant, but sub-monolayer, amount of HCl even at HCl partial pressures typical of the stratosphere. However, quantitative agreement in the size of the uptake is lacking, with a range of close to three orders of magnitude for partial pressures of  $10^{-7}$  Torr at roughly 200 K. One issue is that the specific surface area of the ice was not measured in a number of early studies. Because the ice surface may have some roughness, depending on how it is prepared, a number of these uptakes may be biased high, if the surfaces were assumed to be smooth. Another issue is the partial pressure dependence of the uptake. In accord with a number of uptake measurements of other species on ice, saturated surface coverages are observed at about 2 to  $3 \times 10^{14}$  molecules/cm<sup>2</sup> in experiments where the specific surface area of the ice is well known (e.g. Henson et al.,<sup>11</sup> Hynes et al.,<sup>13</sup> and McNeil et al.<sup>19</sup>). The drop-off into the unsaturated part of the adsorption isotherm appears to vary from experiment to experiment, as the HCl partial pressure is lowered. For example, Hanson and Ravishankara,<sup>10</sup> do not observe a drop off down to partial pressures well below  $10^{-7}$  Torr, whereas others (e.g. Henson et al.<sup>11</sup> and McNeil et al.<sup>19</sup>) see a significant drop-off at higher partial pressures. And so, at the very low partial pressures of the upper troposphere, the surface coverage may be quite unsaturated; even in the stratospheric regime, there may not exist a full monolayer coverage. Some of the most thorough studies have been performed recently. For example, in a coated-wall flow tube study on a variety of ice surfaces at close to 200 K McNeil et al.<sup>19</sup> show that uptakes obeyed conventional Langmuir adsorption isotherms, and that they did not scale as well with the dissociative Langmuir isotherm. A weak adsorption enthalpy of  $-15$  kJ/mole was derived, but the accuracy of this value may be impacted by measurements made at three relatively close temperatures; the true value is likely much higher. Langmuir adsorption constants,  $K_{\text{conc}} = 3.1 \times 10^{-11}, 8.4 \times 10^{-11}$ , and  $3.9 \times 10^{-11}$  cm<sup>3</sup>/molecule, were obtained at 213, 203, and 196 K, respectively. By contrast the work of Henson et al.<sup>11</sup> using a static adsorption technique yields a much lower (one to two orders of magnitude) surface coverage for the same HCl partial pressures and temperatures.

Note that for the same experimental conditions, the uptake may be affected by co-adsorbed species. Studies by Hynes et al.<sup>12</sup> and Sokolov and Abbatt<sup>22</sup> involving co-adsorption of HNO<sub>3</sub> indicate that HNO<sub>3</sub> binds more strongly than HCl, but that the presence of HCl does lead to suppressed HNO<sub>3</sub> uptake relative to behavior on bare ice surfaces. Fernandez et al.<sup>5</sup> also show that HCl uptake is significantly suppressed on a surface that has been exposed to HNO<sub>3</sub>.

Both the thermodynamic and spectroscopic properties of adsorbed HCl suggest that a large fraction dissociates to ions, forms ionic hydrates (especially at low temperatures), and is highly reactive (with ClONO<sub>2</sub>, HOBr and HOCl). Also, adsorption and desorption profiles in flow tubes suggest that uptake occurs via both reversible and irreversible processes, probably related to partitioning to different surface sites such as the ice faces or grain boundaries. These experimental results contrast with initial theoretical calculations that predicted undissociated HCl hydrogen bonded to the ice surface and a very small adsorption probability at stratospheric temperatures (Kroes and Clary<sup>15</sup>); more recent simulations result in higher adsorption energies and theoretical accommodation coefficients of one for 190-K surfaces (Wang and Clary<sup>23</sup>). Molecular dynamics calculations by Gertner and Hynes<sup>7</sup> also show that ionic absorption is thermodynamically favorable by about 5 kcal/mole, facilitated by the role of mobile water molecules on the ice surface that can hydrate the ions. Using ellipsometry McNeil et al.<sup>20</sup> have experimentally shown the presence of a disordered layer on the ice surface, sometimes referred to as the quasi liquid layer, arising from HCl adsorption at low temperatures and partial pressures. By contrast, at HCl partial pressures significantly above those typical of the stratosphere, a thermodynamically stable liquid surface layer forms on the ice, greatly enhancing the total amount of HCl that the surface can absorb (Abbatt et al.<sup>2</sup>). These conditions should be avoided for lab studies as they are not atmospherically appropriate.

- 63. HCl on  $\text{HNO}_3 \cdot n\text{H}_2\text{O}$ .** There was previously severe disagreement between Hanson and Ravishankara<sup>3</sup> ( $\alpha \geq 0.3$ ) for NAT (54 wt%  $\text{HNO}_3$ ), and Leu and coworkers (Moore et al.<sup>5</sup> and Leu et al.<sup>4</sup>). However, subsequent experiments at lower HCl concentrations by Leu and coworkers<sup>2</sup> as well as Abbatt and Molina<sup>1</sup> are generally consistent with Hanson and Ravishankara. The measurements of Hanson and Ravishankara are consistent with  $\alpha = 1$ . The experiments at stratospherically representative HCl concentrations show that  $\text{HNO}_3$ -rich NAT surfaces adsorb significantly less HCl than  $\text{H}_2\text{O}$ -rich surfaces, with the uptake at a fixed temperature determined by the partial pressure of water.<sup>1</sup>

  - (4) Leu, M.-T.; Moore, S. B.; Keyser, L. F. Heterogeneous reactions of chlorine nitrate and hydrogen chloride on Type I polar stratospheric clouds. *J. Phys. Chem.* **1991**, *95*, 7763-7771.
  - (5) Moore, S. B.; Keyser, L. F.; Leu, M. T.; Turco, R. P.; Smith, R. H. Heterogeneous reactions on nitric acid trihydrate. *Nature* **1990**, *345*, 333-335.
- 64. HCl on  $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$ .** Measurements by Watson et al.<sup>9</sup> at 284 K show  $\alpha = 0.15 \pm 0.01$  independent of  $n$  for  $n \geq 8$ . Experimental uptake and, therefore, apparent  $\alpha$  falls off for  $n \leq 8$  ( $\geq 40$  wt%  $\text{H}_2\text{SO}_4$ ). This behavior is also observed at a stratospheric temperature (218 K) by Hanson and Ravishankara.<sup>4</sup> Hanson and Lovejoy<sup>3</sup> reported a value of  $0.75 \pm 0.2$  for 26 wt%  $\text{H}_2\text{SO}_4$  at 272 K. More extensive measurements performed by Robinson et al.<sup>7</sup> at lower temperatures, also yielded higher values, reaching  $1.03 \pm 0.10$  for 39 wt%  $\text{H}_2\text{SO}_4$  at 230 K; they also observed enhanced uptake for 69 wt%  $\text{H}_2\text{SO}_4$  that was attributed to the formation of chlorosulfonic acid. Solubility constraints also controlled earlier low temperature uptake measurements of Tolbert et al.<sup>8</sup> A review of the most recent solubility data is presented in Table 5-6. Molecular beam measurements of HCl impingement on liquid deuterated sulfuric acid surfaces determine the fraction of HCl scattered with no reaction and the fraction that is reactively converted and emitted as DCl. The fraction converted to DCl is assumed to have undergone interfacial transport, representing a lower limit to the mass accommodation coefficient, which varies from  $\sim 0.7$  at 53–55 wt%  $\text{D}_2\text{SO}_4$  to  $\sim 0.1$  near 70 wt% Behr et al.<sup>1</sup> More recent measurements indicate that the conversion fraction is relatively insensitive to HCl kinetic energy over the range of 6 to 140 kJ mol<sup>-1</sup>, and that the conversion fraction for 72 wt%  $\text{D}_2\text{SO}_4$  varies less dramatically, from  $\sim 0.33$  at 213 K to  $\sim 0.47$  at 243 K Behr et al.<sup>2</sup> The basic technique and analysis rationale are reviewed by Nathanson.<sup>5</sup> The impact of organic surfactants on mass accommodation sulfuric acid, including the surprising fact that a surface layer of butanol actually significantly enhances HCl uptake in 213 K, 56–68 wt%  $\text{D}_2\text{SO}_4$  is reviewed in Park et al.<sup>6</sup> These studies strongly indicate that the mass accommodation coefficient for 50–72 wt% sulfuric acid surfaces for temperatures below 243 K is  $> 0.1$ .

- 69. HBr on H<sub>2</sub>O(s) and HNO<sub>3</sub>•nH<sub>2</sub>O.** Hanson and Ravishankara<sup>5,6</sup> have reported large uptake coefficients for HBr on 200-K ice and NAT. Lower limits of >0.3 and >0.2 for ice are reported in the two referenced publications, respectively, and a limit of >0.3 is reported for NAT. No surface saturation was observed, leading to the supposition that HBr, like HCl, dissociates to ions on ice surfaces at stratospheric temperatures. Abbatt<sup>1</sup> measured an uptake coefficient lower limit of >0.03 on water ice at 228 K consistent with Hanson and Ravishankara. Rieley et al.<sup>9</sup> measured an  $\alpha$  of  $1.0 \pm 0.05$  for water ice at 80–120 K. Flückiger et al.<sup>4</sup> report  $\alpha$  values of ~0.2 at 210 K, increasing to ~0.3 at 190 K, while Percival et al.<sup>8</sup> measured an  $\alpha$  of  $0.03 \pm 0.005$  for water ice at T >212 K, and  $\alpha > 0.1$  at T <212 K, attributing the apparent increase in the uptake coefficient to an increase in the surface area of the ice. Hudson et al.<sup>7</sup> report  $\alpha = 0.61 \pm 0.06$  at 140 K, and  $\alpha = 0.24 \pm 0.05$  at 100 K, for HBr pressures ranging from  $3 \times 10^{-8}$  to  $1.4 \times 10^{-7}$  Torr. Equilibrium HBr coverages for ice are reported by Chu and Heron<sup>3</sup> at 188 and 195 K, and by Chu and Chu<sup>2</sup> at 180–220 K. The latter authors also report the formation of various solid HBr hydrates. Given that no surface saturation is observed in the kinetics experiments leads to the supposition that HBr, like HCl, dissociates to ions. In addition to hydrate formation, it is likely that bulk melting of the ice surfaces may occur at stratospheric temperatures and the partial pressures used in the lab, to form thermodynamically stable HBr-H<sub>2</sub>O solutions. Such behavior may not occur in the atmosphere where partial pressures of HBr are typically much lower than those used in the lab.

- 70. HBr on H<sub>2</sub>O(1).** Schweitzer et al.<sup>2</sup> used the droplet train flow reactor technique over a temperature range of 262 to 281 K obtaining values decreasing from 0.16 to 0.068. Li et al.<sup>1</sup> and Zhang et al.<sup>3</sup> used the same technique to measure higher values of  $0.14 \pm 0.02$  at 283 K and  $0.21 \pm 0.3$  at 273 K, respectively. Given the good agreement between the two groups for HCl mass accommodation coefficients on water, there is no obvious reason for the discrepancy of a factor of 2-3 for HBr.

- 71. HBr on  $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$ .** Molecular beam measurements of HBr impingement on liquid deuterated sulfuric acid surfaces determine the fraction of HBr scattered with no reaction and the fraction that reacts, exchanging H for D, and is emitted as DBr. The fraction converted to DBr is assumed to have undergone interfacial transport, representing a lower limit to the mass accommodation coefficient, which varies from ~0.7 at 55 wt%  $\text{D}_2\text{SO}_4$  to ~0.2 near 70 wt% Behr et al.<sup>1</sup> This strongly indicates that the mass accommodation coefficient for HBr is >0.1 for 55–72 wt%  $\text{H}_2\text{SO}_4$  at 213 K.

- 72. HOBr on  $\text{H}_2\text{O}(\text{s})$ .** Abbatt<sup>1</sup> measured an uptake coefficient for water ice of  $2 \times 10^{-3}$  at 228 K. Chu and Chu<sup>3</sup> report an uptake coefficient corrected for porosity effects in the range 0.11 to 0.007 at 190–218 K, with an exponential temperature dependence of  $(3809 \pm 76)/T$ , and in the range  $2 \times 10^{-3}$  to  $6 \times 10^{-4}$  at 223–239 K, with an exponential temperature dependence of  $(4658 \pm 456)/T$ . Chaix et al.<sup>2</sup> measured the uptake coefficient as a function of temperature on three different types of water-ice, obtaining values ranging from ~0.3 at 185 K to ~0.03 at 205 K, with an exponential temperature dependence of  $(4900 \pm 500)/T$ . Mössinger et al.<sup>5</sup> report an uptake coefficient value of 0.003 at 227 K increasing to 0.040 at 205 K. The four sets of results are in reasonable agreement with each other, and the temperature dependence of the uptake coefficient is attributed predominantly to changes in the evaporation rate. The results indicate that the uptake of HOBr on ice cannot be explained with Langmuir-type adsorption isotherms and that the process is not reversible, probably proceeding via the self-reaction of HOBr to form  $\text{Br}_2\text{O}$ , or possibly by formation of hydrates. Using a common precursor model, Flückiger and Rossi<sup>4</sup> have estimated accommodation coefficients  $\alpha$  which are considerably larger than the measured uptake coefficients, with  $\alpha$  values ranging from 0.18 at 215 K to 0.46 at 190 K.

- 80. HI on H<sub>2</sub>O(s).** The uptake of HI has been studied by Chu and Chu<sup>1</sup> in a coated-wall flow tube to be large between 188 and 195 K, in the multi-layer coverage regime. Under their experimental conditions, it is likely that the surface is melting to form a bulk solution and/or hydrates are forming. Percival et al.<sup>2</sup> also report efficient uptake with the same technique between 200 and 233 K, with the uptake coefficient of 0.02 ± 0.004 above 212 K and larger than 0.1 for temperatures below 212 K.  
[Back to Table](#)

- 82. HOI on  $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$ .** Knudsen cell studies by Allanic and Rossi<sup>1</sup> measured uptake at several temperatures for 40, 50, and 70 acid wt%. Time dependent studies show no sign of saturation, so uptake coefficients should correspond to mass accommodation coefficients. Some acid concentration data in the table have been averaged for similar temperatures and rounded to one significant figure. An uncertainty factor of three has been assigned due to the relatively small number of temperature/concentration points studied and a lack of confirming studies from other laboratories. The authors note evidence of HOI disproportionation to form I<sub>2</sub>, however, this second order reaction is unlikely to occur under atmospheric conditions.

- 91. SO<sub>2</sub> on H<sub>2</sub>O(s).** Uptake experiments in coated-wall flow tubes have been conducted by Chu et al.<sup>1</sup> and by Clegg and Abbatt<sup>3</sup> who observe sub-monolayer reversible uptakes for temperatures between 190–211 K and 213–233 K, respectively. Chu et al. report an uptake coefficient of  $1 \times 10^{-5}$  at 191 K. Earlier studies from Clapsaddle and Lamb<sup>2</sup> using chromatographic-like uptake experiments with small ice spheres packed into a column, are in good quantitative agreement with those of Clegg and Abbatt. Both studies report that uptake increases with increasing temperature, unlike most other species that demonstrate more adsorption at lower temperatures. From the partial pressure dependence of the uptake and from the behavior on basic and acidic surfaces, Clegg and Abbatt infer the uptake occurs by formation of bisulfite on the surface, in the quasi-liquid layer on the surface of ice.

- 92. SO<sub>2</sub> on H<sub>2</sub>O(l).** Using a droplet train flow reactor Worsnop et al.<sup>7</sup> measured an  $\alpha$  of  $0.11 \pm 0.02$  with no significant temperature variation over a temperature range of 260–292 K. Ponche et al.<sup>4</sup> measured  $0.13 \pm 0.01$  at 298 K, in agreement with the earlier measurement. Shimono and Koda<sup>6</sup> estimated an  $\alpha$  of 0.2 at 293.5 K from analysis of pH-dependent uptake coefficients in a liquid impingement technique. Schurath et al.<sup>5</sup> used a coaxial flow liquid jet to obtain a value of 0.1 at 298 K. Boniface et al.<sup>1</sup> performed more extensive droplet train flow reactor measurements at high pH to relieve solubility constraints, obtaining a negative temperature dependence with  $\alpha$  values ranging from  $0.43 \pm 0.4$  at 264 K to  $0.175 \pm 0.015$  at 291 K, their data can be fit to  $\alpha/(1-\alpha) = \exp(-\Delta G^\ddagger_{\text{obs}}/RT)$ , where  $\Delta G^\ddagger_{\text{obs}} = -(7.6 \pm 0.6)$  kcal/mol +  $(29.2 \pm 2.1)$

cal mol<sup>-1</sup> K<sup>-1</sup> T(K). Donaldson et al.<sup>2</sup> have used second harmonic generation spectroscopy to detect a chemisorbed SO<sub>2</sub> surface species which was predicted from earlier uptake measurements by Jayne et al.,<sup>3</sup> this surface complex may play a role in SO<sub>2</sub> heterogeneous reactions on aqueous surfaces.

[Back to Table](#)

**94. H<sub>2</sub>S on H<sub>2</sub>O(1).** Boniface et al.<sup>1</sup> performed droplet train flow reactor measurements over at 260–298 K at high pH to relieve solubility constraints, measured uptake coefficients were consistent with  $\alpha \geq 0.05$ .

- (1) Boniface, J.; Shi, Q.; Li, Y. Q.; Chueng, J. L.; Rattigan, O. V.; Davidovits, P.; Worsnop, D. R.; Jayne, J. T.; Kolb, C. E. Uptake of gas-phase SO<sub>2</sub>, H<sub>2</sub>S, and CO<sub>2</sub> by aqueous solutions. *J. Phys. Chem. A* **2000**, *104*, 7502-7510, doi:10.1021/jp000479h.

**95. H<sub>2</sub>SO<sub>4</sub> on H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** Poschl et al.<sup>2</sup> measured  $0.43 < \alpha < 1.0$  for 73–98 wt% H<sub>2</sub>SO<sub>4</sub> at 303 K in a wetted wall flow tube. Lower temperatures and acid concentrations would be expected to lead to larger values of  $\alpha$ . As discussed in Poschl et al.<sup>2</sup> this contradicts an indirect measurement of  $0.02 < \alpha < 0.09$  at 42.5 wt% at 298 K by Van Dingenen and Raes<sup>3</sup> in a photochemical aerosol reactor. The Poschl et al.<sup>2</sup> result is consistent with room temperature  $\alpha$  values very near that measured for (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> particles in an aerosol flow reactor by Jefferson et al.<sup>1</sup>

\* $\gamma$  is temperature dependent

## 5.14 Notes to Table 5-2

1. **O<sub>3</sub> on H<sub>2</sub>O(s).** Ozone loss on pure ice is highly inefficient, with uptake coefficients in the range of 10<sup>-8</sup> to 10<sup>-9</sup> for partial pressures between 2 × 10<sup>-8</sup> and 10<sup>-6</sup> atm at 223 and 258 K, as measured in an ice-coated column. The uptake coefficients are dependent on the ozone partial pressure, increasing at low partial pressures Langenberg et al.<sup>1</sup>

[Back to Table](#)

- (1) Langenberg, S.; Schurath, U. Ozone destruction on ice. *Geophys. Res. Lett.* **1999**, 26, 1695-1698.

2. **O<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub>(s).** Very low ozone decomposition efficiencies for reaction on coarse (3 μm dia.) and fine (0.1 μm dia., partially hydroxylated) γ-alumina and coarse (3 μm dia.) α-alumina were measured in flowing and static systems by Hanning-Lee et al.<sup>3</sup> at temperatures ranging between 212 and 473 K. Based on measured BET surface areas,  $\gamma_s$  ranged from 2 × 10<sup>-11</sup> to 4 × 10<sup>-10</sup> over the 212 to 298 K temperature range.  $\gamma_s$  for γ-alumina at lower temperatures exceeded those for α-alumina. Results are roughly consistent with earlier, unpublished flow tube data from L. F. Keyser and from fluidized bed reactor studies of Alebić-Juretić et al.<sup>1</sup> Note that  $\gamma_s$  based on geometric surface particle surface areas would be significantly (10<sup>4</sup>-10<sup>7</sup>) larger. Additional fluidized bed reactor studies by Alebić-Juretić et al.<sup>2</sup> demonstrated that room temperature uptake are initially first order in O<sub>3</sub>, but change to a slower second order reaction at longer exposure times. Klimovskii et al.<sup>4</sup> reported an initial uptake coefficient ( $\gamma_0$ ) of 1 × 10<sup>-4</sup> on a γ-alumina surface at 293 K assuming a geometric surface area, BET surface correction presumably would have yielded a lower value. Michel et al.<sup>5,6</sup> reported Knudsen cell uptake studies at 296 K on α-alumina particles that yielded  $\gamma_0$  values of (8 ± 5) × 10<sup>-5</sup> and (1.4 ± 0.3) × 10<sup>-4</sup> after BET surface area corrections. Sullivan et al.<sup>9</sup> used a coated wall flow reactor to obtain 298 K  $\gamma_0$  values of 7 × 10<sup>-6</sup> to 1.6 × 10<sup>-5</sup> for α-alumina powder films exposed to no more than [O<sub>3</sub>] of 10<sup>13</sup> cm<sup>-3</sup> after BET surface area correction. Higher [O<sub>3</sub>] yielded lower apparent  $\gamma_0$ s. Usher et al.<sup>10</sup> demonstrated the pretreatment of α-alumina with HNO<sub>3</sub> vapor reduced O<sub>3</sub> Knudsen cell  $\gamma_0$  values by ~70%. Mogili et al.<sup>7</sup> measured O<sub>3</sub> uptake on α-alumina particles in a room temperature environmental chamber obtaining an uptake coefficient of (3.5 ± 0.9) × 10<sup>-8</sup> for dry (RH ≤ 1%) particles that fell to (4.5 ± 1.1) × 10<sup>-9</sup> for measurements at 19% RH. Roscoe and Abbatt<sup>8</sup> demonstrated spectroscopically that there is a competition for surface sites when gas phase ozone and water vapor are exposed to the alumina surface.

3. **O<sub>3</sub> + NaCl.** The reaction of O<sub>3</sub> with NaCl is slow. Il'in et al.<sup>3</sup> measured the loss of O<sub>3</sub> in a coated reactor over the temperature range 223–305 K, and found the same uptake coefficients,  $\gamma \sim 10^{-6}$ , independent of

temperature, for NaCl and NH<sub>4</sub>NO<sub>3</sub> and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, suggesting that even the small uptake is not due to reaction with the chloride. Alebić-Juretić<sup>2</sup> did not observe any uptake on NaCl powders using a fluidized bed reactor but did not report an upper limit to the uptake coefficient. Akimoto and coworkers<sup>6,7</sup> reported an upper limit of  $\gamma_0 < 1 \times 10^{-5}$  on NaCl. When the NaCl was mixed with 0.5–1% w:w FeCl<sub>3</sub>,  $\gamma_0$  increased to  $3 \times 10^{-2}$  and production of gaseous Cl<sub>2</sub> was observed with yields from 25–50% of the ozone taken up. With 0.1% FeCl<sub>3</sub>, no production of Cl<sub>2</sub> was observed but the initial uptake coefficient was still  $3 \times 10^{-2}$ . These experiments were carried out with a Knudsen cell using multiple salt layers and the measured initial uptake coefficients were converted to the reported values using the pore diffusion model of Keyser et al.<sup>4,5</sup> Abbatt and Waschewsky<sup>1</sup> followed O<sub>3</sub> in a flow tube containing deliquesced 1–5 μm NaCl particles (75% RH); no significant loss was observed on unbuffered particles or particles buffered at pH of 7.2. An upper limit of  $\gamma_0 < 1 \times 10^{-4}$  was derived from these measurements.

4. **O<sub>3</sub> + NaBr and KBr.** Mochida et al.<sup>4</sup> did not observe any uptake of O<sub>3</sub> on NaBr or KBr powders, from which they derived an upper limit of  $\gamma < 1 \times 10^{-5}$ . Hirokawa et al.<sup>2</sup> reported production of gas phase Br<sub>2</sub> from the reaction of O<sub>3</sub> with NaBr only when water vapor was added so that the salt was near deliquescence.

Uptake of O<sub>3</sub> and production of gas phase Br<sub>2</sub> has been observed for deliquesced NaBr salt on a glass surface.<sup>1</sup> Production of Br<sub>2</sub> has also been measured by Hunt et al.<sup>3</sup> in the reaction of O<sub>3</sub> with deliquesced NaBr particles in the dark in an aerosol chamber; the production of Br<sub>2</sub> exceeded that from known aqueous phase chemistry by about an order of magnitude, suggesting that a surface reaction of O<sub>3</sub> with bromide at the air-solution interface was occurring with a reaction probability of  $\gamma_0 = (1.9 \pm 0.8) \times 10^{-6}$  ( $2\sigma$ ).

The uptakes of O<sub>3</sub> by frozen salt solutions and cold liquid solutions containing bromide have been studied in a coated wall flow tube from 233 to 273 K by Oldridge and Abbatt.<sup>5</sup> Br<sub>2</sub> was the sole product formed. Reaction kinetics were well described by a combination of a bulk reaction in the associated solution and a surface reaction component, so that the overall ozone uptake coefficients increased with decreasing ozone concentrations. The similarity between the results on both liquid solutions and frozen solutions implied the reaction was occurring only with the liquid component of the substrates. Using glancing angle LIF and Raman spectroscopy, Wren et al.<sup>6</sup> have studied the reactions of ozone with both frozen and unfrozen bromide solutions with sea water concentrations. They demonstrate that the kinetics proceed one to two orders of magnitude faster on the frozen substrates than on the corresponding unfrozen solutions.

- 5. O<sub>3</sub> + KI.** Brown et al.<sup>1,2</sup> report that KIO<sub>3</sub> forms on single crystal, water-free KI surfaces with a reaction probability of  $1.4 \times 10^{-4}$ . On room temperature KI solutions, Sakamoto et al.<sup>8</sup> report that ozone exposure yields gas-phase I<sub>2</sub> and small amounts of IO (ratio of I<sub>2</sub> to IO >100). The reaction kinetics are indicative of a Langmuir-Hinshelwood mechanism, exhibiting saturation in the gas-phase yields as both ozone and iodide concentrations are increased. The reaction forming I<sub>2</sub> proceeds more rapidly with increasing acidity for pH <4, but there is a pH-independent pathway operative to pH 11.
- Complex chemistry for ozone reacting at the surface of solutions containing iodide and other reactants is illustrated from studies of solution microdroplet analysis by electrospray ionization (Pillar et al.,<sup>5</sup> Enami et al.,<sup>3</sup> and Hayase et al.<sup>4</sup>). In particular, a number of researchers have shown that surfactants and/or dissolved organic species can affect the rate of iodide oxidation by ozone (Hayase et al.,<sup>4</sup> Shaw and Carpenter,<sup>9</sup> Reeser et al.,<sup>6</sup> and Rouviere et al.<sup>7</sup>).

- 6. O<sub>3</sub> + sea salt.** Akimoto and coworkers<sup>11,14</sup> reported uptake coefficients for O<sub>3</sub> on synthetic and natural sea salt powders of  $\sim 1 \times 10^{-3}$  using a Knudsen cell with multiple salt layers. Similar uptake coefficients were reported for the hydrates of MgBr<sub>2</sub> and CaBr<sub>2</sub>. These are the initial uptake coefficients after correction for the available surface area using the pore diffusion model of Keyser et al.<sup>9,10</sup> The measured values before this correction was applied were about a factor of 20 larger. Given the uncertainty associated with these corrections, the final values derived have a large uncertainty associated with them as well. When FeCl<sub>3</sub> was added to synthetic sea salt (Fe/Na weight ratio of 1%), the uptake coefficient increased by an order of magnitude to  $(3.2 \pm 1.1) \times 10^{-2}$ . Br<sub>2</sub> was the gas phase product, with variable yields up to 100% of the O<sub>3</sub>.

lost. The enhanced reactivity of sea salt compared to NaCl and NaBr is due to the significant amounts of surface-adsorbed water (SAW) present on sea salt; the component of sea salt present in the second highest concentration is magnesium chloride which forms a stable hydrate and is quite hygroscopic. Reactions with powders of MgCl<sub>2</sub>•6H<sub>2</sub>O and sea salt are often observed to be similar to reaction with aqueous salt solutions (see note on SO<sub>2</sub> uptake). The formation of Br<sub>2</sub> is favored over Cl<sub>2</sub> by a number of factors: (1) surface segregation of bromide ions<sup>3,4,15</sup> in mixed solid crystals of NaCl and NaBr, (2) higher solubility of NaBr which increases its concentration in the surface layer as a mixture of NaCl and NaBr crystallizes, (3) faster oxidation of Br<sup>-</sup> compared to Cl<sup>-</sup><sup>2,5,6,13</sup> (4) solution phase chemistry of chloride and bromide ion mixtures that favors the production of gas phase bromine compounds,<sup>2,13</sup> (5) enhanced interfacial bromide ion concentrations compared to chloride ions at the air-water interface of aqueous solutions of mixed salts.<sup>7,8</sup> The yields of I<sub>2</sub> from exposure of sea water to ozone have been studied by Carpenter et al.<sup>1</sup> under ambient ozone concentrations. I<sub>2</sub> was quantified by conversion to small particles, which were sized and counted. On frozen sea-salt solutions, gas phase Br<sub>2</sub> was formed by exposure of O<sub>3</sub> (44 ppbv to 2.9 ppmv) to frozen sea salt solutions, at temperatures below 272 K.<sup>12</sup> No other products were reported and the production of Br<sub>2</sub> scaled with increasing O<sub>3</sub>.

7. **O<sub>3</sub> + organic surfaces.** Reactive initial uptake of ozone occurs on organic substrates that contain unsaturated carbon-carbon bonds, whereas uptake to substrates that are fully saturated is minimal. This reaction occurs not only with simple alkenes, but with electron-rich conjugated systems such as PAHs as well. Ozone adds across carbon-carbon double bonds forming an ozonide, which then falls apart into more reactive intermediates. The product distributions are complex. Initial uptake coefficients are highly dependent upon the chemical nature of the substrate, ranging from values of roughly 10<sup>-3</sup> on pure alkene

aerosol particles such as oleic acid, to much lower values of  $10^{-6}$  or below with PAH-coated particles. A more detailed discussion of this complex chemistry is given in two review articles: Kolb et al.<sup>2</sup> and Abbatt et al.<sup>1</sup>

An overview of current issues in the uptake of atmospheric trace gases by aerosols and clouds. *Atmos. Chem. Phys.* **2010**, *10*, 10561-10605, doi:10.5194/acp-10-10561-2010.

- 8. OH + H<sub>2</sub>O(s).** Cooper and Abbatt<sup>1</sup> measured initial irreversible OH uptake coefficients of ~0.1 for water ice between 205–230 K; these decayed to  $\gamma = 0.03 \pm 0.02$  after repeated exposure to OH. Self-reaction to form H<sub>2</sub>O or H<sub>2</sub>O<sub>2</sub> was indicated by the lack of observable gas phase products despite observation of first-order OH loss. It can not be ruled out that contamination of the ice surface drove the initial reactivity.

- 12. OH + NaCl.** Ivanov et al.<sup>2</sup> measured the uptake of OH on solid NaCl and on NH<sub>4</sub>NO<sub>3</sub> over the temperature range from 245–340 K using a fast flow discharge reactor with a coated rod along the axis and EPR detection of OH. The initial values of the uptake coefficient approached 10<sup>-2</sup>. The OH was generated from the reaction of H atoms with excess NO<sub>2</sub>; it is not clear whether NO<sub>2</sub> might have also reacted with the salt surface. Given that the uptake coefficients were similar for NaCl and NH<sub>4</sub>NO<sub>3</sub>, the uptake likely does not reflect oxidation of the chloride. The pseudo-steady state value,  $\gamma_{ss}$ , was measured to be  $4 \times 10^{-3}$  at 298 K and the temperature dependence was described by  $\gamma_{ss} = (1.2 \pm 0.7) \times 10^{-5} \exp[(1750 \pm 200)/T]$ . This value is quite close to later measurements by Park et al.<sup>6</sup> who see little dependence of the uptake coefficient on relative humidity, up to 38% at room temperature. Product studies have been performed by Sjostedt and Abbatt<sup>8</sup> who have exposed desiccated NaCl salts to gas-phase OH in a coated-wall flow tube at 298 and 253 K. Gas-phase Br<sub>2</sub> is formed with a yield of 0.6, relative to the loss of OH. The source of the Br<sub>2</sub> is the trace Br<sup>-</sup> impurity in commercial, high purity NaCl<sub>(s)</sub>. BrCl was formed at a considerably smaller yield, 0.008. Humidification of the salt surface led to more sustained production but somewhat smaller yields. Aerosol chamber studies by Finlayson-Pitts and coworkers showed that there was no Cl<sub>2</sub> production from NaCl particles when OH was generated by reaction of O(<sup>1</sup>D) from photolysis of O<sub>3</sub> at relative humidities below the deliquescence point of NaCl; above the deliquescence point, however, a rapid reaction of OH with Cl<sup>-</sup> at the interface to generate gas phase Cl<sub>2</sub> is observed.<sup>3,5</sup> Because the mechanism is uncertain, and clearly must involve multiple steps, a unique value of the reaction probability for this interface reaction could not be obtained. At 269 K Frinak and Abbatt<sup>1</sup> have exposed acidic solutions containing molar levels of NaCl to gas-phase OH. The gas-phase product observed is Br<sub>2</sub>, unless considerable OH exposure has reduced Br<sup>-</sup> levels in the solution, in which case the product is Cl<sub>2</sub>. The source of the Br<sub>2</sub> is the trace Br<sup>-</sup> impurity in commercial, high purity NaCl<sub>(s)</sub>. At neutral pH, the products were below detection limit. Shaka et al.<sup>7</sup> and Laskin et al.<sup>4</sup> have both exposed chloride solutions to gas-phase OH, observing changes in solution alkalinity and chloride concentrations, respectively. This is another indication that chloride ions in solution are readily heterogeneously oxidized by OH. Laskin et al. report an uptake coefficient of  $\geq 0.1$  at room temperature. However, the OH concentrations were not measured which may lead to uncertainty in this value.

- 14. OH + organic surfaces.** It has been shown through a large number of studies that the OH radical is efficiently lost on organic surfaces via condensed phase reactions that add oxygenated functional groups to the organics, and lead to some carbon-carbon bond breakage as well. The uptake coefficient for OH loss has been studied at room temperature on both chemically reduced and oxidized surfaces, and found to be larger than 0.1, as determined both by monitoring loss of OH directly and by monitoring loss of specific organics within the aerosol. A more detailed discussion of this complex chemistry is given in three review articles: Kolb et al.,<sup>3</sup> George and Abbatt,<sup>2</sup> and Abbatt et al.<sup>1</sup>

- 15. HO<sub>2</sub> + H<sub>2</sub>O(s) and H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Uptake of HO<sub>2</sub> on ice and super-cooled 55 wt.% sulfuric acid at 223 K has been demonstrated to be limited by HO<sub>2</sub> surface saturation by Cooper and Abbatt.<sup>1</sup> They argue that self-reaction, presumably  $2\text{HO}_2 \rightarrow \text{H}_2\text{O}_2 + \text{O}_2$  is controlling measured uptake coefficients of  $0.025 \pm 0.005$  for ice and  $0.055 \pm 0.020$  for 55 wt.% H<sub>2</sub>SO<sub>4</sub>. Thornton and Abbatt<sup>4</sup> report room temperature aerosol flow reactor submicron droplet measurements on 47–50 wt% H<sub>2</sub>SO<sub>4</sub>, without HO<sub>2</sub> scavenger species, yielding  $\gamma < 0.01$ . Gershenzon et al.<sup>2</sup> measured  $\gamma > 0.2$  for 80 and 96 wt.% H<sub>2</sub>SO<sub>4</sub> at 243 K and Hanson et al.<sup>3</sup> measured a lower limit for 28 wt% H<sub>2</sub>SO<sub>4</sub> at 275 K of 0.07. However, large gas phase diffusion corrections mean these values are consistent with  $\gamma = 1$ . Thornton et al.<sup>5</sup> have used available experimental data to develop a parameterized HO<sub>2</sub> self-reaction uptake model valid for pH < 6 aqueous droplets and gas phase HO<sub>2</sub> generation rates exceeding  $1 \times 10^5 \text{ cm}^{-3} \text{ s}^{-1}$ . They also assess the relative role of Cu<sup>++</sup> catalyzed oxidation of HO<sub>2</sub> in aqueous aerosols.

- 16. HO<sub>2</sub> + (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>(aq) and NaCl(aq).** HO<sub>2</sub> uptake on aerosol particles has been studied in aerosol flow tubes. At high HO<sub>2</sub> concentrations detected by CIMS, Thornton and Abbatt<sup>4</sup> observed loss of HO<sub>2</sub> on aqueous ammonium sulfate particles, buffered to pH 5.1 at RH 42% and room temperature. An uptake coefficient of 0.1 could describe the kinetics, but the HO<sub>2</sub> decays were best fit by second-order kinetics consistent with a bulk-phase reaction between dissolved HO<sub>2</sub> species, when using literature HO<sub>2</sub> solubility and bulk liquid-phase rate constants. Because of the second-order kinetics, it was inferred that the uptake

coefficient would be substantially smaller at lower (atmospheric) HO<sub>2</sub> gas-phase concentrations.<sup>5</sup> This prediction is confirmed by the detailed study of George et al.<sup>1</sup> which examined HO<sub>2</sub> uptake at gas phase concentrations between 10<sup>8</sup> and 10<sup>9</sup> molecules/cm<sup>3</sup> in an aerosol flow tube using LIF detection methods. The uptake coefficients measured were between 0.003 and 0.02 on deliquesced particles of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, NaCl and NH<sub>4</sub>NO<sub>3</sub>. These results are not in agreement with the work performed using LIF by Taketani et al.<sup>2,3</sup> who reported uptake coefficients on ammonium sulphate (0.11 to 0.19, 45 to 75% RH), sodium chloride (0.1, 50 to 75% RH) and sea salt (0.1, 35 to 75% RH) at atmospheric HO<sub>2</sub> concentrations about two orders of magnitude lower (<10<sup>8</sup> molecules/cm<sup>3</sup>) than those of Thornton and Abbatt, but similar to those of George et al. George et al. observed much more efficient loss when transition metals were present in solution, highlighting the importance of working with clean aerosol samples. As well, there are complex dependencies of the kinetics on HO<sub>2</sub> concentration and on reaction time. However, these dependencies do not appear to explain the large discrepancy between the results from the Taketani et al. and George et al. experiments, performed under nominally similar conditions. In the absence of transition metal impurities such as iron or copper ions, there is no known reactive chemistry that will deplete HO<sub>2</sub> as rapidly as observed in the Taketani et al. experiments.

17. **HO<sub>2</sub> + NaCl(s) and KCl(s).** Gershenson and coworkers<sup>2,5</sup> used a combination of matrix isolation EPR and gas phase EPR with a fast flow tube to measure the uptake of HO<sub>2</sub> on NaCl from 245–335 K. Early studies by Gershenson et al.<sup>2</sup> measured values of  $\gamma = 1.8 \times 10^{-2}$  for KCl and  $1.6 \times 10^{-2}$  for NaCl, both at 295 K, supplementing an even earlier value of  $\gamma \sim 8 \times 10^{-3}$  measured by Gershenson and Purmal.<sup>3</sup> In later studies on NaCl<sup>5</sup> the uptake was reported to remain constant for at least 30 min, so this is likely to be a steady-state value,  $\gamma_{ss} = 1.2 \times 10^{-2}$  at 295 K. The temperature dependence is given by  $\gamma_{ss} = (5.7 \pm 3.6) \times 10^{-5} \exp[(1560 \pm 140)/T]$ . Above 330 K, the uptake coefficient was significantly smaller than expected from this temperature dependence. The data are indistinguishable, within experimental error, from the uptake of HO<sub>2</sub> on NH<sub>4</sub>NO<sub>3</sub>, suggesting that the uptake of HO<sub>2</sub> likely involves recombination on the surface rather than oxidation of the chloride. The surface recombination was interpreted in terms of a combined Eley-Rideal and Langmuir-Hinshelwood mechanism. The addition of small amounts of water vapor decreased the uptake coefficient for HO<sub>2</sub>; the authors attributed this to water adsorption on the active sites. Another possibility is formation of HO<sub>2</sub>-H<sub>2</sub>O complexes whose uptake and recombination on the surface is not as fast as for uncomplexed HO<sub>2</sub>. A study by Loukhovitskaya et al.<sup>4</sup> using a coated-wall flow tube finds temperature dependent uptake coefficients on salt surfaces, reporting uptake coefficient between 10<sup>-3</sup> and 10<sup>-2</sup> at room temperature. They report that gas-phase H<sub>2</sub>O<sub>2</sub> was observed as a product, indicative of self-reaction. George et al.<sup>1</sup> and Taketani et al.<sup>6</sup> report uptake coefficients of less than 0.0004 and 0.01, respectively, on dry NaCl aerosol in aerosol flow tubes using HO<sub>2</sub> concentrations of 10<sup>8</sup> to 10<sup>9</sup> molecules/cm<sup>3</sup>. The small upper limit for this process from George et al., measured at low concentrations of HO<sub>2</sub>, suggests that the earlier measurements may have been dominated by radical recombination on salt surfaces.

- 18. HO<sub>2</sub> + (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>(s).** George et al.<sup>1</sup> report uptake coefficients of less than 0.0004 on dry (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> aerosol in an aerosol flow tube using HO<sub>2</sub> concentrations of 10<sup>8</sup>-10<sup>9</sup> molecules/cm<sup>3</sup>. Taketani et al.<sup>2</sup> report a considerably larger value, 0.04, measured with the same experimental approach. The discrepancy between these measurements is mirrored by an equivalent disagreement between these groups' measurements of HO<sub>2</sub> loss on aqueous salt solutions. The source of the disagreement is not clear but trace metal impurities have the potential to drive very efficient uptake and might be the cause of the higher values by Taketani et al.

- 19. H<sub>2</sub>O (g) + Al<sub>2</sub>O<sub>3</sub>(s).** Isotopic thermal programmed desorption studies at 300 K by Elam et al.<sup>2</sup> show that H<sub>2</sub>O dissociatively absorbs on  $\alpha$ -alumina surfaces and that initial uptake coefficient ( $\gamma_0$ ) is ~0.1. Pre-hydroxylation or long term exposure to water vapor decreases the H<sub>2</sub>O uptake coefficient nearly exponentially. Al-Abadleh et al.<sup>1</sup> used FTIR techniques to study water vapor uptake at 296 K on  $\alpha$ -alumina crystal 0001 surfaces as a function of relative humidity (RH). Below 10% RH uptake is dissociative, but molecular absorption dominates uptake between 10 and 70% RH. FTIR spectra of water absorbed on both  $\alpha$ -alumina and  $\gamma$ -alumina powder surfaces are similar to those on 0001 crystal surfaces. Goodman et al.<sup>3</sup> used FTIR to show that  $\alpha$ -alumina surfaces saturated with HNO<sub>3</sub> vapor has the same water absorption isotherm as untreated samples at 296 K.

- 20. H<sub>2</sub>O<sub>2</sub> + Al<sub>2</sub>O<sub>3</sub>(s).** Zhao et al.<sup>3</sup> measured H<sub>2</sub>O<sub>2</sub> uptake on a bed of ~35nm  $\alpha$ -alumina particles in a solid sample flow reactor as a function of relative humidity at room temperature and ambient pressure. BET surface area was used in analyzing uptake coefficients. Uptake was RH dependent, which was varied over a wide range (2–76%). Gas phase hydrogen peroxide leaving the reactor was scrubbed and quantified using liquid chromatography. Uptake was largely irreversible with reactive uptake ~75% at low RH rising to ~85% at high RH. Reported uptake coefficients ( $\gamma$ ) were lower at higher RHs:  $\gamma(RH-2\%) = (1.21 \pm 0.04) \times 10^{-7}$ ;  $\gamma(RH-21\%) = (0.84 \pm 0.07) \times 10^{-7}$  and  $\gamma(RH \geq 42\%) = (0.72 \pm 0.04) \times 10^{-7}$ . Use of BET surface areas

probably led to underestimated  $\gamma$  values. Uptake experiments were performed for 30 minutes; larger uptake coefficients may have characterized shorter uptake times. The authors also reported largely reversible H<sub>2</sub>O<sub>2</sub> uptake coefficients on SiO<sub>2</sub> submicron particles that were about an order of magnitude lower than those measured for alumina.<sup>3</sup>

Wang et al.<sup>2</sup> report Knudsen cell studies, also on  $\alpha$ -alumina and other mineral oxide surfaces at room temperature and very low RH. For  $\alpha$ -alumina the measured gas phase products also indicate catalytic decomposition. Measured  $\gamma_0$  values using BET surface areas were  $(1.00 \pm 0.11) \times 10^{-4}$  for  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>,  $(1.66 \pm 0.23) \times 10^{-5}$  for MgO,  $(9.70 \pm 1.05) \times 10^{-5}$  for Fe<sub>2</sub>O<sub>3</sub> and  $(5.22 \pm 0.9) \times 10^{-5}$  for SiO<sub>2</sub>. Their  $\gamma_0$  value for  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> is roughly a factor of a thousand higher than the steady-state  $\gamma$  values reported by Zhao et al.<sup>3</sup>

Romanias et al.<sup>1</sup> used a coated wall flow reactor with solid films of ~20 nm  $\gamma$ -alumina particles to measure H<sub>2</sub>O<sub>2</sub> uptake coefficients over a RH range of 0.003 to 73% and a temperature range of 268–329 K. Near ultraviolet (315–400 nm) illumination had no effect on uptake. BET surface area measurements were also used to calculate uptake coefficients. They observed that longer exposure times lead to saturated surfaces, so initial  $\gamma_0$  uptake coefficients as well as steady-state  $\gamma$  values were reported. Desorption measurements showed reversible H<sub>2</sub>O<sub>2</sub> uptake was 5% or less of total uptake. Initial uptake values were dependant on both RH and T; for instance,  $\gamma_0$  (for 0.003% RH and 300 K) =  $(9.0 \pm 2.7) \times 10^{-4}$ , is nearly constant for (0.003–0.02% RH) then falls off to  $\sim 2 \times 10^{-5}$  at 73% RH. The steady-state uptake coefficient also decreases at higher RH values,  $\gamma$ (280 K) falls from about  $2.5 \times 10^{-5}$  at about 0.005% RH to  $\sim 5 \times 10^{-7}$  at RH of 73%. Clearly adsorbed water vapor competes with irreversible H<sub>2</sub>O<sub>2</sub> chemisorption. At fixed RH the initial uptake of H<sub>2</sub>O<sub>2</sub> increases with falling temperature,  $\gamma_0(0.03\% \text{ RH}) = 8.7 \times 10^{-4} / (1 + 5.0 \times 10^{13} \exp(-9700/T))$  rising from  $2.0 \times 10^{-4}$  at 320 K to  $8.8 \times 10^{-4}$  at 268 K.<sup>1</sup> Note that the low RH  $\gamma_0$  values reported in this work are the same order of magnitude as the dry  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> value reported by Wang et al.<sup>2</sup>

Given that there is little reason to expect that  $\alpha$ -alumina and  $\gamma$ -alumina have the same initial uptake coefficients, not to mention similar RH or temperature dependencies, the available data will support only a conservative upper limit estimate of  $\gamma_0 < 5 \times 10^{-3}$ .

21. **NO<sub>2</sub> + H<sub>2</sub>O(I).** Value for  $\gamma$  of  $(6.3 \pm 0.7) \times 10^{-4}$  at 273 K (Tang and Lee<sup>9</sup>) was achieved by chemical consumption of NO<sub>2</sub> by SO<sub>3</sub><sup>2-</sup>; their stopped-flow measurement was probably still affected by surface saturation, leading to the measurement of a lower limit. Ponche et al.<sup>7</sup> measured an uptake coefficient of  $(1.5 \pm 0.6) \times 10^{-3}$  at 298 K, which was also probably subject to saturation limitations. Mertes and Wahner<sup>5</sup> used a liquid jet technique to measure a lower limit of  $\gamma \geq 2 \times 10^{-4}$  at 278 K, and they observed partial conversion of the absorbed NO<sub>2</sub> to HONO. Msibi et al.<sup>6</sup> used a cylindrical/annular flow reactor to derive  $\gamma = (8.7 \pm 0.6) \times 10^{-5}$  on pH = 7 deionized water surfaces and  $(4.2 \pm 0.9) \times 10^{-4}$  on pH = 9.3 wet ascorbate surfaces; it seems likely that these results are also subject to surface saturation given the gas/surface interaction times involved in the experiment. Harrison and Collins<sup>3</sup> performed aerosol flow reactor experiments on deliquescent sodium chloride and ammonium sulfate droplets at 279 K obtaining reactive uptake coefficients in the range of  $(2.8–10) \times 10^{-4}$ , probably with some surface saturation constraints. Cheung et al.<sup>1</sup> used a droplet train flow reactor to show that the reactive uptake coefficient for NO<sub>2</sub> at number densities between  $10^{13}$  and  $10^{16}$  on pure water at 273 K is  $< 5 \times 10^{-4}$ , contradicting many of the earlier experiments. Cheung et al. also used a bubble train reactor to demonstrate that the reactive uptake of NO<sub>2</sub> is second order, so that experimental uptake coefficients will be dependent on gas phase NO<sub>2</sub> concentrations.

Colussi and co-workers<sup>2,4,10</sup> measured the adsorption/reaction of gaseous NO<sub>2</sub> on ~293 K aqueous microstreams by measuring the nitrate ion content by electrospray mass spectrometry after the microstreams break up into small charged droplets. In Yabushita et al.<sup>10</sup> the aqueous microstreams were doped with alkali salts (NaCl, NaBr and NaI), in Kinugawa et al.<sup>4</sup> doping agents were cationic and anionic

surfactants (tetrabutylammonium bromide, tetra decyltrimethylammonium bromide and potassium perfluorooctanesulfonate) as well as NaBr, and in Colussi et al.<sup>2</sup> the additives were dicarboxylic acids representing components of secondary organic aerosol (SOA) including malonic, glutaric and glutamic acids with low enough pK<sub>1</sub> values to dissociate to monoanions. The nitrate detected is assumed to be produced by the surface reaction:  $2 \text{NO}_2 + \text{H}_2\text{O} \rightarrow \text{HONO} + \text{HNO}_3$ . This experimental process is semi-quantitative, Colussi et al. estimate that the non-detectable nitrate levels in undoped water microstreams indicate a  $\gamma_0 < 2 \times 10^{-7}$  for pure water. However, when the aqueous microstreams are doped with gas/liquid interface active anions or cations, the apparent  $\text{NO}_2 \gamma_0$  values increase nonmonotonically with electrolyte concentrations peaking at  $\gamma_0 \sim 10^{-4}$  for [NaX] concentrations of ~1 mM.<sup>10</sup> Colussi et al.<sup>2</sup> also present theoretical models of  $\text{NO}_2$  interactions with water clusters containing  $\text{Cl}^-$  in a aqueous interfacial environment that identify electrostatic interactions strong enough to potentially enhance the reactivity of adsorbed  $\text{NO}_2$ .

Sosedova et al.<sup>8</sup> measured the uptake of radioactive  $^{13}\text{NO}_2$  (half life 10 min.), which can be detected at extremely low concentrations, by deliquesced sodium salts of hydroquinone (1,4-dihydroxybenzene) and gentisic acid (2,5-dihydroxybenzoic acid) in a flow tube reactor at 296 K and 40% RH. Reactant  $^{13}\text{NO}_2$  and product  $\text{HO}^{13}\text{NO}$  are trapped on chemically selective denuder surfaces and quantified by counting  $^{13}\text{N}$  decay gamma rays. Observed reactive uptake coefficients ( $\gamma_s$ ) ranged from  $\sim 5 \times 10^{-4}$  to  $\sim 6 \times 10^{-3}$ . The measured time dependence of  $\text{NO}_2$  reactive uptake was fitted to a kinetic model of reactant consumption in the droplet phase using the  $\text{NO}_2$  mass accommodation coefficient and the rate constants for dissolved  $\text{NO}_2$  with the deprotonated phenolic compounds as variables, yielding an estimated room temperature bulk liquid mass accommodation coefficient:  $\alpha = 0.024$  (+0.018/-0.003). If accurate for pure water, it indicates that the lower reactive uptake coefficients measurements above are subject to some degree of surface saturation.

Data are consistent with a reactive uptake coefficients less than  $1 \times 10^{-2}$  for 270–295 K and a liquid-phase second-order hydrolysis of  $\text{NO}_2$  to HONO and  $\text{HNO}_3$  which depends on temperature and pH. However, the interplay between mass accommodation, possible surface reaction, and bulk reaction may be complex.

22.  **$\text{NO}_2 + \text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$ .** Kleffman et al.<sup>2</sup> performed bubble tube reactor uptake measurements for 0–98 wt% acid at 298 K and for 44.6 and 56.1 wt% from 250–325 K. At 298 K, measured uptake coefficients varied between 6 and  $3 \times 10^{-7}$  with a minimum near 70 wt%. Most measurements at 44.6 and 56.1 wt%

overlapped within their error limits and showed little temperature dependence although there is evidence that uptake increases at the lowest temperatures. The data can all be captured with a recommended value of  $5 \times 10^{-7}$  with an uncertainty factor of three.

This recommendation is consistent with earlier upper limits of  $1 \times 10^{-6}$  by Baldwin and Golden<sup>1</sup> for 96 wt% at 295 K and  $5 \times 10^{-6}$  for 70 wt% between 193 and 243 K by Saastad et al.<sup>3</sup> Kleffman et al.<sup>2</sup> conclude that their uptake measurements are mass accommodation limited; however, it is not clear that their values are not influenced by bulk or surface reaction of two NO<sub>2</sub> with H<sub>2</sub>O to form HONO and HNO<sub>3</sub> at lower acid wt% values and the formation of nitrosyl sulfuric acid at higher acid concentrations. Kleffman et. al.<sup>2</sup> did perform separate static wetted wall reactor studies showing the formation of gas phase HONO at acid concentrations below 60 wt%. It is more likely that reactive uptake is a controlling factor and the measured uptakes are solubility and/or reaction rate limited. Thus, the mass accommodation coefficient may be much larger than the recommended uptake values.

- 23. NO<sub>2</sub> + Al<sub>2</sub>O<sub>3</sub>.** Miller and Grassian<sup>5</sup> observed NO<sub>2</sub> adsorbed reactively on  $\gamma$ -alumina using FTIR and UV spectroscopy to observe surface nitrite and nitrate. Szanyi et al.<sup>7</sup> used FTIR and thermal programmed desorption/mass spectrometry to determine products formed on  $\gamma$ -alumina surfaces at 300 K, observing nitrites and nitrates (at higher NO<sub>2</sub> only nitrate). Exposure to water vapor converted most bridging nitrates to bidentate and monodentate nitrates. Baltrusaitis et al.<sup>1</sup> also used FTIR to observe monodentate, bidentate and bridging nitrates products on both  $\alpha$ -alumina and  $\gamma$ -alumina particles at 296 K. They also observed that co-absorbed water solvates surface nitrates. Underwood et al.<sup>8-10</sup> report Knudsen cell studies measuring  $\gamma_0$  values on  $\gamma$ -alumina particles of  $2 \times 10^{-8}$ ,  $2.0 \times 10^{-8}$ , and  $2.2 \times 10^{-8}$  at 298 K based on BET surface area corrections and either Keyser, Moore, Leu (KLM) formulation<sup>4</sup> or linear mass dependent (LMD) corrections for porosity, with the KML and LMD corrections leading to very similar values.<sup>8</sup> They also report larger  $\gamma_0$  values for  $\alpha$ -alumina of  $9.3 \times 10^{-6}$  and  $9.1 \times 10^{-6}$ .<sup>8,10</sup> Underwood et al.<sup>10</sup> also suggest a final “multiple collision” that would raise the  $\gamma_0$  values for  $\gamma$ -alumina by factor of 1.1 and  $\alpha$ -alumina by 9.4. This proposed correction is not included in the recommended upper limits. Börensen et al.<sup>2</sup> report diffuse reflectance FTIR measurements of uptake on  $\gamma$ -alumina showing that the reaction order is  $1.86 \pm 0.1$  in NO<sub>2</sub>. They report BET corrected  $\gamma_0$  values varying linearly from  $7.3 \times 10^{-10}$  to  $1.3 \times 10^{-8}$  as [NO<sub>2</sub>] was increased from  $2.5 \times 10^{13}$  to  $8.5 \times 10^{14}$ . Rubasinghe and Grassian<sup>6</sup> irradiated nitrate absorbed on  $\gamma$ -alumina particles with broad band light (>300 nm) as a function of RH (at ~1, 20, 45 and 80% and with and without gas phase O<sub>2</sub>) observing photolytic production of gas phase NO (primary product), NO<sub>2</sub> and N<sub>2</sub>O. Guan et al.<sup>3</sup> report  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> BET uptake coefficients at 298 K for both dark measurements ( $9.9 \pm 4.8 \times 10^{-10}$ ) and simulated sunlight (350–700 nm) conditions ranging from  $2.55$  to  $3.33 \times 10^{-9}$  for light fluxes of 0.45–2.25 mW/cm<sup>2</sup>. They also showed that NO<sub>2</sub> uptake was independent of its gas phase concentration between 2.7 and  $53.8 \times 10^{14}$  molecules/cm<sup>3</sup>, so surface saturation was probably not an issue.<sup>3</sup> However, they assumed that all NO<sub>2</sub> uptake resulted in surface NO<sub>3</sub><sup>-</sup> production and integrated the observed nitrate bands to estimate nitrate surface concentrations. For gaseous mixtures of NO<sub>2</sub> and O<sub>2</sub> they determined that the nitrate production rate reaction order was  $0.960 \pm 0.111$  for NO<sub>2</sub> and  $0.620 \pm 0.083$  for O<sub>2</sub>.<sup>3</sup> Note, that they cite Börensen et al. (2000), but do not discuss the fact that Zellner’s group measured a NO<sub>2</sub> uptake order on  $\gamma$ -alumina of  $1.86 \pm 0.1$ . Wu et al.<sup>11</sup> report the effect of temperature (250–318 K) on “dry air” NO<sub>2</sub> uptake and nitrate production on  $\gamma$ -alumina surfaces using a DRIFTS set-up. They obtained geometrical  $\gamma_0$  values increasing from  $(7.42 \pm 0.77) \times 10^{-4}$  at 318 K to  $(23.0 \pm 2.58) \times 10^{-4}$  at 250 K, corresponding to  $\gamma_0$ (BET) values of  $(2.58 \pm 0.27) \times 10^{-10}$  and  $(8.17 \pm 0.92) \times 10^{-10}$ . There is no discussion of the very large (> $10^6$ ) differences between  $\gamma_0$ (BET) and  $\gamma_0$ (GEO).

Given the currently available data and the extremely low uptake coefficients reported for BET estimated surface areas, only upper limits for  $\gamma_0$ ’s on  $\alpha$ -alumina and  $\gamma$ -alumina are listed.

- 24. NO<sub>2</sub>/N<sub>2</sub>O<sub>4</sub> + NaCl.** Schroeder and Urone reported that NO<sub>2</sub> at Torr concentrations reacted with NaCl to form ClNO.<sup>7</sup> Subsequently, Finlayson-Pitts<sup>4</sup> showed that the reaction continued at ppm concentrations of NO<sub>2</sub> and estimated a lower limit to the uptake coefficient for NO<sub>2</sub> of  $5 \times 10^{-8}$ , assuming the reaction was first order in NO<sub>2</sub>. Winkler et al.<sup>11</sup> used XPS to follow the increase in nitrate during the reaction of NO<sub>2</sub> with NaCl and reported that the rate was proportional to the square of the NaCl surface sites and the square root of NO<sub>2</sub>. Vogt and Finlayson-Pitts<sup>8-10</sup> used diffuse reflectance Fourier transform infrared spectrometry (DRIFTS) to follow the formation of nitrate and showed that the reaction was second order in NO<sub>2</sub>; assuming that N<sub>2</sub>O<sub>4</sub> was the reactant, the uptake coefficient was measured to be  $(1.3 \pm 0.6) \times 10^{-4}$  ( $1\sigma$ ). Peters and Ewing<sup>6</sup> followed the formation of nitrate on single crystal NaCl(100) and also found the reaction was second order in NO<sub>2</sub>. Assuming that N<sub>2</sub>O<sub>4</sub> is the reactant, the uptake coefficient was  $(1.3 \pm 0.3) \times 10^{-6}$ , two orders of magnitude less than reported by Vogt and Finlayson-Pitts. However, in the presence of 9.5 mbar water vapor, the uptake coefficient increased by a factor of about 100. It is likely that the difference is that their single crystals did not hold significant amounts of surface adsorbed water, whereas the powders used by Vogt and Finlayson-Pitts are known to hold significant amounts of SAW<sup>2</sup> which enhances the reactivity through mobilization of the nitrate ions and exposure of fresh NaCl during the reaction. Caloz et al.<sup>3</sup> measured using a Knudsen cell an upper limit of  $<10^{-7}$  for uptake of NO<sub>2</sub> on NaCl and  $< 2 \times 10^{-7}$  for uptake on KBr, with the reaction being first order in NO<sub>2</sub>. Yoshitake<sup>13</sup> also used DRIFTS to study this reaction and reported that for “dry” NaCl, the reaction was second order in NO<sub>2</sub> with an uptake coefficient assuming the reactant is N<sub>2</sub>O<sub>4</sub> of  $(4 \pm 2) \times 10^{-5}$ . However, if the NaCl had been pretreated with water vapor, the uptake was first order in NO<sub>2</sub> with  $\gamma = (1.5 \pm 0.2) \times 10^{-8}$ . Karlsson and Ljungstrom<sup>5</sup> generated NaCl particles and measured the loss of chloride and formation of nitrate using ion chromatography on particles collected on filters; they obtained a lower limit for the reaction probability of  $3 \times 10^{-4}$ . Surprisingly, the conversion of NO<sub>2</sub> to nitrate decreased as the relative humidity increased from 9 to 79%. These reactions are sufficiently slow that they are unlikely to be important in the atmosphere. Abbatt and Waschewsky<sup>1</sup> measured the loss of NO<sub>2</sub> in a flow tube containing deliquesced 1–5  $\mu$ m NaCl particles (75% RH); no significant loss was observed on unbuffered particles or particles buffered at pH of 7.2 or having pH of 0.3 using HCl. An upper limit of  $\gamma_0 < 1 \times 10^{-4}$  for the uptake of NO<sub>2</sub> was derived from

these measurements. Yabushita et al.<sup>12</sup> have recently shown using ESI-MS that uptake of NO<sub>2</sub> to aqueous droplets, yielding the nitrate anion, is facilitated by the presence of halide anions, perhaps through the formation of a complex with NO<sub>2</sub> on the surface.

- 26. NO<sub>2</sub>/N<sub>2</sub>O<sub>4</sub> + sea salt.** Sverdrup and Kuhlman<sup>2</sup> measured the uptake of NO<sub>2</sub> on artificial sea salt using the NO<sub>2</sub> loss measured in a flow tube lined with the salt. The uptake coefficient was reported to increase from  $10^{-7}$  to  $10^{-6}$  as the relative humidity increased from 44% to 88%. Langer et al.<sup>1</sup> used diffuse reflectance Fourier transform infrared spectrometry to follow nitrate formation on synthetic sea salt and found the reaction was approximately second order ( $1.8 \pm 0.2$ ) in NO<sub>2</sub> in He carrier gas but approximately first order ( $1.2 \pm 0.2$ ) in NO<sub>2</sub> in air. Assuming that N<sub>2</sub>O<sub>4</sub> was the reactant in He,  $\gamma_{ss} = 1 \times 10^{-4}$ , and assuming NO<sub>2</sub> is the reactant in air,  $\gamma_{ss} = 1 \times 10^{-8}$ . These reactions are sufficiently slow that they are unlikely to be important in the atmosphere.

- (1) Fenter, F. F.; Rossi, M. J. Heterogeneous reaction of  $\text{NO}_3$  with ice and sulfuric acid solutions: Upper limits for the uptake coefficients. *J. Phys. Chem. A* **1997**, *101*, 4110-4113.
- 28.  $\text{NO}_3 + \text{H}_2\text{O(l)}$ .** Rudich et al.<sup>3,4</sup> used wetted-wall flow tube techniques to measure uptake coefficients for  $\text{NO}_3$  on pure water and aqueous NaCl, NaBr, NaI, and  $\text{NaNO}_2$  solutions. These studies were extended to other aqueous solutions by Imamura et al.<sup>1</sup> Uptake on pure water was consistent with reaction of  $\text{NO}_3$  to produce  $\text{HNO}_3$  and OH. Uptake coefficients with solutions containing  $\text{I}^-$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{NO}_2^-$ , and other anions were larger and scaled with anion concentration, indicating electron transfer reactions to produce  $\text{NO}_3^-$ . Reactions with these anions and/or adsorbed organic contaminants may well dominate the reactive uptake of  $\text{NO}_3$  by real atmospheric aqueous surfaces. The  $\gamma$  of  $(2.0 \pm 1.0 \times 10^{-4})$  at 273 K determined for pure water by Rudich et al. is significantly lower than the lower limit of  $2.5 \times 10^{-3}$  from Thomas and co-workers as quoted by Mihelcic et al.<sup>2</sup> and further discussed in Thomas et al.,<sup>6</sup> who also dispute that reactive uptake coefficient on pure water reported by Rudich et al. is due to nitric acid production. A detailed analysis of uptake coefficients for KI aqueous solutions by Rudich et al.<sup>3</sup> indicated that the  $\text{NO}_3$  mass accommodation coefficient is  $>0.04$ ,<sup>3</sup> but this result may be biased due to reactive uptake by interfacial  $\text{I}^-$ . Single droplet uptake results on Alizarin Red S dye and NaCl solutions at 293 K by Schütze and Herrman<sup>5</sup> suggest a value an order of magnitude smaller (see Table 5.1).

- 29.  $\text{NO}_3 + \text{NaCl}$ .** Also see note for  $\text{NO}_3 + \text{H}_2\text{O(l)}$ . Recommended value for the initial uptake coefficient on solid NaCl is based on work of Seisel et al.,<sup>4,5</sup> Gershenson and coworkers,<sup>1</sup> and Gratpanche and Sawerysyn<sup>2</sup>. Seisel et al.<sup>4,5</sup> used a Knudsen cell with mass spectrometric and laser-induced fluorescence detection of the  $\text{NO}_3$ . Salt powders from  $60\text{--}630 \mu\text{m}$  in size were used, as well as spray-deposited samples; no dependence on the sample mass for powders or between powders and the spray-deposited samples was observed so no corrections for diffusion into underlying layers were applied. They obtained values for  $\gamma_0$  of  $(4.9 \pm 3) \times 10^{-2}$  and  $(4.6 \pm 4) \times 10^{-2}$  ( $1\sigma$ ), respectively. Gershenson and coworkers used flow reactors with ESR and MS detection and measured the loss of  $\text{NO}_3$  on an axially located rod coated with salt; they interpret their results, and the associated value of  $\gamma_0$  derived from their data based on a multi-step mechanism involving adsorption and then reaction of  $\text{NO}_3$  on the salt. The value for  $\gamma_0$  is sensitive to several unknown parameters in the model, and they give a range from  $(0.2\text{--}3.9) \times 10^{-2}$ . Gratpanche and Sawerysyn<sup>2</sup> used a flow tube coated with NaCl and ESR detection of  $\text{NO}_3$ , and reported a value of  $(1.7 \pm 1.2) \times 10^{-2}$  ( $1\sigma$ ); on very dry NaCl, no uptake was observed, again indicating the importance of small amounts of water for the reaction. Gershenson et al.<sup>1</sup> reported that the uptake coefficient decreased by about a factor of 20 over about half an hour, suggesting that the steady state value of  $\gamma_{ss}$  is approximately  $1.5 \times 10^{-3}$ . Zelenov et al. reported that the uptake coefficient for  $\text{NO}_3$  on NaCl (and NaBr; see next note)<sup>7,8</sup> could be fit by a time-dependent term and a time-independent term:  $\gamma(t) = \gamma_0 \exp(-t/\tau) + \gamma_{ss}$ . They observed

that  $\gamma_{ss}$  depends on the type of salt, as well as the  $\text{NO}_3$  and water concentrations, while  $\gamma_0$  depended only on the type of salt and  $\text{NO}_3$  concentration. They concluded that the products are chemisorbed Cl atoms. No temperature dependence has been observed over the temperature range 258–301 K by Gratpanche and Sawerysyn,<sup>2</sup> consistent with only an ~10% change in the uptake coefficient from 293 to 373 K observed by Gershenson et al.<sup>1</sup>

The uptake of  $\text{NO}_3$  on aqueous solutions of NaCl has been measured at 273 K by Rudich et al.<sup>3</sup> and at 293 K by Thomas et al.<sup>6</sup>  $\text{NO}_3$  reacts in solutions with the halide ions. The measured uptake coefficients varied from  $(0.8\text{--}6) \times 10^{-3}$  for solutions of activity ranging from 0.008 to 0.45 at 273 K<sup>3</sup> and was reported to be  $>2 \times 10^{-3}$  on 0.1 M NaCl at 293 K.<sup>6</sup>

Reactive  $\text{NO}_3$  uptake on humidified sea salts  $\text{NaX}$  ( $X=\text{Cl}, \text{Br}$ ) under steady state conditions. *Khim. Fiz.* **2003**, *22*, 58–70.
  - (8) Zelenov, V. V.; Aparina, E. V.; Gershenson, M. Y.; Il'in, S. D.; Gershenson, Y. M. Kinetic mechanisms of atmospheric gases uptake on sea salt surfaces. 4. Initial step of  $\text{NO}_3$  uptake on salts NaCl and NaBr. *Khim. Fiz.* **2003**, *22*, 37–48.
- 30.  $\text{NO}_3 + \text{NaBr}$  and  $\text{NaI}$ .** Also see notes for  $\text{NO}_3 + \text{NaCl}$  and  $\text{NO}_3 + \text{H}_2\text{O(l)}$ . Recommended value of  $\gamma_0$  for the reaction with solid NaBr is based on reported values of  $0.16 \pm 0.08$ ,<sup>4</sup>  $0.20 \pm 0.10$ ,<sup>5</sup> a range of 0.1 to 0.3<sup>1</sup> and  $0.11 \pm 0.06$ <sup>2</sup> (all errors cited are  $1\sigma$ ). Gershenson et al.<sup>1</sup> observed a decrease of about a factor of two with time, suggesting that  $\gamma_{ss} \sim 0.05$ . Gratpanche and Sawerysyn<sup>2</sup> found a slight negative temperature dependence,  $\gamma_0 = (1.6^{+1.8}_{-0.9} \times 10^{-3}) \exp[(1210 \pm 200)/T]$  over the range from 243–293 K. Gershenson et al.<sup>1</sup> also reported a small (30%) decrease in  $\gamma_0$  from 293 to 373 K. Zelenov et al.<sup>6,7</sup> reported that the uptake coefficient for  $\text{NO}_3$  on NaBr (and NaCl; see preceding note) could be fit by a time-dependent term and a time-independent term:  $\gamma(t) = \gamma_0 \exp(-t/\tau) + \gamma_{ss}$ . They observed that  $\gamma_{ss}$  depends on the type of salt, as well as the  $\text{NO}_3$  and water concentrations, while  $\gamma_0$  depended only on the type of salt and  $\text{NO}_3$  concentration. They concluded that the products are bromine atoms in agreement with the observations of the branching ratio as well as the mass balance by Seisel et al.<sup>4,5</sup>

Rudich et al.<sup>3</sup> measured the uptake of  $\text{NO}_3$  on aqueous KI solutions;  $\text{NO}_3$  is taken up and reacts with  $\text{I}^-$  in solution. Uptake coefficients increased with the concentration of  $\text{I}^-$ , ranging from  $\gamma = 0.9 \times 10^{-3}$  at  $5 \times 10^{-6}$  M KI to  $3.2 \times 10^{-3}$  at a concentration of  $8 \times 10^{-5}$  M.

- 32.  $\text{N}_2\text{O}_5 + \text{H}_2\text{O(s)}$ .** Leu<sup>4</sup> and Hanson and Ravishankara<sup>1</sup> measured nearly identical values of 0.028 ( $\pm 0.011$ ) and 0.024 ( $\pm 30\%$ ) in the 195–202 K range on relatively thick ice films in coated wall flow tubes. Quinlan et al.<sup>5</sup> measured a maximum value for  $\gamma$  on ice surfaces at 188 K of 0.03 in a Knudsen cell reactor. The average of these three studies is 0.027 with a standard deviation of 0.003. Hanson and Ravishankara<sup>2,3</sup> presented new and re-analyzed data as a function of ice thickness, with a value of ~0.008 for the thinnest ice sample, rising to 0.024 for the thickest. From these data there would appear to be no strong dependence on temperature, at least over the 188–195 K range. It is unclear whether the measured dependence on ice film thickness is due to added porosity surface area in the thicker films or decreased ice film integrity in thinner films. The error estimate in the table is driven by the possible systematic error due to unresolved film thickness effects rather than the small statistical error among the “thick film” values from the three groups.
- Zondlo et al.<sup>6</sup> report the formation of a supercooled  $\text{H}_2\text{O}/\text{HNO}_3$  liquid layer at 185 K as a reaction product, forming NAT or NAD only after decreasing the relative humidity below the ice frost point. This effect is similar to that resulting from the interaction of gaseous  $\text{HNO}_3$  or  $\text{ClONO}_2$  with the ice surface. These authors measured  $\gamma = (7 \pm 3) \times 10^{-4}$  at 185 K for the reaction of  $\text{N}_2\text{O}_5$  with this supercooled liquid layer.

33. **N<sub>2</sub>O<sub>5</sub> + H<sub>2</sub>O(l).** This reaction has now been studied widely on both pure water and on aqueous surfaces. The kinetics of the reaction are dependent on a number of conditions, as described below. On pure waer, Van Doren et al.<sup>21</sup> measured  $\gamma_s$  of  $0.057 \pm 0.003$  at 271 K and  $0.036 \pm 0.004$  at 282 K using a droplet train uptake technique, indicating that the reaction has a negative temperature dependence. George et al.<sup>6</sup> also used a droplet train technique to measure  $\gamma_s$  of  $(3.0 \pm 0.2) \times 10^{-2}$  (262 K),  $(2.9 \pm 1.2) \times 10^{-2}$  (267 K),  $(2.0 \pm 0.2) \times 10^{-2}$  (273 K),  $(1.6 \pm 0.8) \times 10^{-2}$  (276 K), and  $(1.3 \pm 0.8) \times 10^{-2}$  (277 K) on pure water, while Schweitzer et al.<sup>18</sup> used the same approach for pure water and salt solutions between 262 and 278 K, obtaining similar results. Msibi et al.<sup>14</sup> measured a smaller  $\gamma$  of  $2.5 \times 10^{-3}$  for water adsorbed on a denuder flow tube well under 66–96% relative humidity conditions at room temperature, making the nature of the surface unclear. After correction for gas-phase diffusion effects, Schütze and Herrmann<sup>17</sup> measured a  $\gamma$  of  $1.1 \times 10^{-2}$  at 293 K using a single suspended droplet flow reactor method that was probably constrained by nitrate build-up in the droplet's surface layer.

A number of other groups have measured the uptake coefficients of N<sub>2</sub>O<sub>5</sub> on aqueous solutions, where the reactivity of the N<sub>2</sub>O<sub>5</sub> is with the water solvent molecules. These studies include: Mozurkewich and Calvert<sup>13</sup> on NH<sub>3</sub>/H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O aerosols in an aerosol flow tube, Hu and Abbatt<sup>10</sup> on (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> aerosols at 297 K in an aerosol flow tube, Mentel and co-workers<sup>12,22</sup> on sodium sulfate and sodium nitrate particles in a large aerosol chamber, Thornton et al.<sup>20</sup> measured uptake on malonic acid aerosols in an aerosol flow tube, Hallquist et al.<sup>9</sup> studied ammonium sulfate and sodium nitrate particles, and Griffiths et al.<sup>7</sup> measured uptake on a variety of soluble organic acids with and without ammonium sulfate present. Note that the studies conducted with sodium chloride or sea salt as the solute are listed in the N<sub>2</sub>O<sub>5</sub> + NaCl note below.

Overall, the  $\gamma$  values measured at high relative humidity by Van Doren et al., Mozurkewich and Calvert, Hu and Abbatt, Thornton et al., Hallquist et al., and Griffiths et al., and those from experiments with NaCl at high relative humidity (Benke et al.<sup>2</sup> and Thornton and Abbatt<sup>19</sup>) are quite consistent when temperature and RH effects are factored in, yielding uptake coefficients in the 0.02 to 0.04 range at room temperature. The lower values from the Louis Pasteur (George et al. and Schweitzer et al.) and Birmingham (Msibi et al.) groups appear to have much less pronounced temperature dependence and are inconsistent with the other measurements. The same function used to fit the N<sub>2</sub>O<sub>5</sub> uptake on sulfuric acid as a function of temperature and concentration, discussed below, has been extended to the Van Doren et al. and Hu and Abbatt data for pure water and very high RH aerosols. See note on N<sub>2</sub>O<sub>5</sub> + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l) for the functional fit and its error discussion.

However, other factors that affect the uptake coefficient include: 1. At low relative humidities, the  $\gamma$  values are reduced from the values close to water saturation, with the uptake coefficient scaling linearly with the water content of the aerosol below a specific relative humidity (roughly 50% RH). This is indicative of a competition for water of a reactive intermediate formed via N<sub>2</sub>O<sub>5</sub> initial uptake (see in particular Thornton et al.,<sup>20</sup> Thornton and Abbatt,<sup>19</sup> Hallquist et al.,<sup>9</sup> and Griffiths et al.<sup>7</sup>). 2. At high aerosol nitrate concentrations the kinetics are slower, falling below 0.001 in some cases, indicative that a reactive intermediate along the reaction pathway is less stable under such conditions (see Mentel and co-workers<sup>12,22</sup> and Hallquist et al.<sup>9</sup>). Note that high nitrate levels may develop in laboratory experiments where high N<sub>2</sub>O<sub>5</sub> concentrations are used, potentially biasing the uptake coefficients to lower values than are atmospherically significant. This may be manifest as an uptake coefficient that is dependent on the concentration of N<sub>2</sub>O<sub>5</sub> used.<sup>20</sup> 3. By varying particle diameters, the reacto-diffusive length has been measured to be 48 nm at 50% RH on malonic acid aqueous particles, indicating that this process is not fully occurring at the surface of the particle and that there might be a particle-size dependence to the uptake coefficient.<sup>20</sup> 4. The uptake coefficients can be substantially suppressed when large organic molecules, such as those formed by the reaction of ozone with alpha-pinene or those present in humic-like materials are present in/on aqueous inorganic aerosol.<sup>15</sup> The uptake coefficients in these systems can be substantially below 0.01, with only a few weight percent of organic present. Also, monolayers of surfactant organics on aqueous particles can have the same effect (Thornton and Abbatt<sup>19</sup> and McNeill et al.<sup>11</sup>). 5. Finally, as observed with pure water by Van Doren et al.<sup>21</sup>, there is a negative temperature dependence to the uptake coefficient over the small temperature range that has been studied.<sup>7,9</sup> For example, the most recent measurements by Griffiths et al.<sup>8</sup> show the uptake coefficient changing from 0.035 to 0.005 from 263 to 303 K at 50% RH. A new parameterization of laboratory kinetics that takes

into account the water, nitrate, dissolved organic, and chloride concentrations has been published by Bertram and Thornton.<sup>3</sup>

Beyond the laboratory, the uptake coefficient of N<sub>2</sub>O<sub>5</sub> has been measured from decays on ambient (outdoor air) particles in an aerosol flow tube. It has been observed that the uptake coefficients are smallest (<0.005) when the organic content of the particles is high. Uptake coefficients of 0.03 were measured, but only on some occasions and when the sulphate/organic content of the particles was highest.<sup>4</sup> Additional studies with ambient particles have confirmed the wide range of uptake coefficients under ambient conditions, observing a substantial amount of day-to-day variability that may be due to variable particle phase and/or organic composition.<sup>15,16</sup>

- 34. N<sub>2</sub>O<sub>5</sub> + HNO<sub>3</sub>•3H<sub>2</sub>O(s).** Hanson and Ravishankara<sup>1</sup> have measured  $\gamma = 0.0006 (\pm 30\%)$  near 200 K. They re-analyzed their results and give additional data as a function of ice thickness (Hanson and Ravishankara<sup>2,3</sup>), deriving a value of  $3 \times 10^{-4}$  for the thinnest nitric acid trihydrate (NAT) covered ice layer, with values up to three times higher for thicker NAT-covered ice layers. As in the case of uptake on water ice this may be due to increased surface area from porosity in the thicker films, or less integrity in the thinner films. The uncertainty listed in the Table is driven by this observed effect. All of the Hanson et al. data are in poor agreement with the  $\gamma = 0.015 \pm 0.006$  reported by Quinlan et al.<sup>4</sup> from their Knudsen cell measurements; this measurement may have been biased by formation of a super-cooled aqueous nitric acid surface and is judged to be unreliable. It is possible that the uptake coefficients will be affected by whether the NAT surfaces are water-rich or poor.

- 35. N<sub>2</sub>O<sub>5</sub> + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** This reaction has been intensively studied between 195 and 296 K for a wide range of H<sub>2</sub>SO<sub>4</sub> wt.% values using four complementary experimental techniques. Data are available from aerosol flow tube studies (Fried et al.,<sup>3</sup> Hanson and Lovejoy,<sup>5</sup> Hu and Abbatt,<sup>7</sup> and Hallquist et al.<sup>4</sup>), coated wall flow tube studies (Hanson and Ravishankara<sup>6</sup> and Zhang et al.<sup>14</sup>), a stirred Knudsen cell (Manion et al.<sup>9</sup>) and droplet train studies (Van Doren et al.<sup>12</sup> and Robinson et al.<sup>11</sup>). All studies have yielded  $\gamma_s$  between ~0.05 and 0.20 with modest dependence on surface H<sub>2</sub>SO<sub>4</sub> wt.% and temperature. The Knudsen cell studies, aerosol flow tube studies at higher N<sub>2</sub>O<sub>5</sub> exposure and the ternary H<sub>2</sub>SO<sub>4</sub>/HNO<sub>3</sub>/H<sub>2</sub>O studies of Zhang et al.<sup>14</sup> all illustrate that significant levels of HNO<sub>3</sub> in the H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O solutions will reduce  $\gamma$  measurably; this fact explains some of the scatter in aerosol flow tube studies and the surface saturation evident in the Knudsen cell studies. The "nitrate effect" reduction of  $\gamma$  was also studied in extensive aerosol chamber studies at 193.6 K by Wagner et al.<sup>13</sup> The effect of  $5.0 \times 10^{-7}$  Torr HNO<sub>3</sub> on  $\gamma$  as a function of temperature at two water vapor concentrations are plotted in Zhang et al.;<sup>14</sup> the decrease in  $\gamma$  is greatest at low temperatures, approaching a factor of 2–5 between 200 and 195 K.

Experimental data on sulfuric acid surfaces between 40 and 80 wt% sulfuric acid deemed to be free of saturation effects, plus the pure water uptake data of Van Doren et al.<sup>12</sup> and high relative humidity ammonium sulfate aerosol uptake data of Hu and Abbatt<sup>7</sup> were all fit to a polynomial expression to yield a single model describing  $\gamma$  for N<sub>2</sub>O<sub>5</sub> uptake valid between 0 and 80 wt% H<sub>2</sub>SO<sub>4</sub> and 180 to 300 K (Robinson et al.<sup>11</sup>). The form of this function is:  $\gamma_0 = \exp(k_0 + k_1/T + k_2/T^2)$ , where T is the temperature in K. The parameters k<sub>0</sub>, k<sub>1</sub>, and k<sub>2</sub> obtained from the best-fit are:

$$k_0 = -25.5265 - 0.133188wt + 0.00930846wt^2 - 9.0194 \times 10^{-5}wt^3$$

$$k_1 = 9283.76 + 115.345wt - 5.19258wt^2 + 0.0483464wt^3$$

$$k_2 = -851801 - 22191.2\text{wt} + 766.916 \text{wt}^2 - 6.85427 \text{wt}^3$$

where wt is the weight percentage of H<sub>2</sub>SO<sub>4</sub>.

The overall error of applying the uptake function provided here consists of two components. One is the standard deviation of the model-calculated value with respect to measured data,  $\sigma_m$ , which is given by

$$\sigma_m = \sqrt{\frac{\sum_{i=1}^N \left(1 - \frac{\gamma_i}{\gamma_{model}}\right)^2}{N-1}}.$$

The other is the standard deviation of relative experimental measurement error from the mean,  $\sigma_d$ , which is given by

$$\sigma_d = \sqrt{\frac{\sum_{i=1}^N \left(\frac{\Delta\gamma_i}{\gamma_i}\right)^2}{N(N-1)}}.$$

The overall error is

$$\sigma = \sqrt{\sigma_m^2 + \sigma_d^2}.$$

(These formulations are also applied below in the error estimation for the ClONO<sub>2</sub> + H<sub>2</sub>O and HCl, BrONO<sub>2</sub> + H<sub>2</sub>O, and HOCl + HCl reaction system. For N<sub>2</sub>O<sub>5</sub>, the error is estimated to be 15% ( $1\sigma$ ), with  $\sigma_m = 14.7\%$  and  $\sigma_d = 2.9\%$ ).

Liquid trough flow reactor studies on 60–80 wt% H<sub>2</sub>SO<sub>4</sub> at 273–280 K by Bertram and co-workers demonstrated that adsorbed single and dual component coatings of organics like 1-hexadeconal, 1-octadeconal and stearic acid could reduce  $\gamma$  by well over a factor of 10, while coatings of phytanic acid had little effect. Even 0.75 monolayer coatings of 1-octadeconal reduced  $\gamma$  by a factor of 10.<sup>1,2,8</sup> Park et al.<sup>10</sup> impinged a molecular beam of N<sub>2</sub>O<sub>5</sub> on 72 wt% H<sub>2</sub>SO<sub>4</sub> at 216 K, observing that sub-monolayer coverage of 1-butanol and 1-hexanol reduced bare acid reactive uptake coefficients from ~0.15 to ~0.10 and 0.06, respectively.

- 36.  $\text{N}_2\text{O}_5 + \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}(\text{s})$ .** Zhang et al.<sup>1</sup> used coated flow tube techniques to measure the uptake of  $\text{N}_2\text{O}_5$  on solid sulfuric acid monohydrate over a temperature range of 200 to 225 K. The measurement values of  $\gamma$  were significantly higher at 200 K ( $\gamma \sim 1 \times 10^{-3}$ ) than at 225 K ( $\gamma \sim 10^{-4}$ ) and were well fit by  $\log \gamma = [4.78 - 0.0386T(\text{K})]$ . Acid-rich  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  surfaces had a lower  $\gamma$  than water rich surfaces ( $\log \gamma = [0.162 - 0.789 \times \log p_{\text{H}_2\text{O}}]$  where  $p_{\text{H}_2\text{O}}$  is their experimental water vapor partial pressure in Torr).

- 37.  $\text{N}_2\text{O}_5 + \text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}(\text{s})$ .** Hanson and Ravishankara<sup>1</sup> studied  $\text{N}_2\text{O}_5$  uptake by frozen 57.5 and 60 wt.%  $\text{H}_2\text{SO}_4$  as a function of temperature and relative humidity. The 57.5 wt% surface was not sensitive to relative humidity and was slightly more reactive ( $\gamma = 0.008$  vs 0.005) at 205 K than at 195 K. Reaction probabilities on the 60 wt% surface dropped off with temperature and relative humidity.

- 38.  $\text{N}_2\text{O}_5 + \text{HCl}$  on  $\text{H}_2\text{O}(\text{s})$ .** Leu<sup>3</sup> measured  $\gamma = 0.028 \pm 0.011$  at 195 K, while Tolbert et al.<sup>5</sup> measured a lower limit of  $1 \times 10^{-3}$  at 185 K. Seisel et al.<sup>4</sup> measured  $\gamma \sim 0.03$  at 200 K using a Knudsen flow reactor with a range of  $\text{HCl}$  flows. The uptake coefficient at low  $\text{HCl}$  flows is only slightly enhanced compared to the uptake on a pure ice surface.  $\text{ClNO}_2$  was observed as the product in these studies. These experiments were done at high  $\text{HCl}$  levels probably leading to a liquid water/acid surface solution (Abbatt et al.<sup>1</sup>). Indeed, Hanson and Ravishankara<sup>2</sup> point out that a pure ice surface is readily converted to one with a thin NAT coating even with low  $\text{N}_2\text{O}_5$  partial pressures, making this reaction difficult to study on pure ice surfaces.

- (1) Hanson, D. R.; Ravishankara, A. R. Heterogeneous chemistry of HBr and HF. *J. Phys. Chem.* **1992**, 96, 9441-9446.
- 43. N<sub>2</sub>O<sub>5</sub> + NaCl.** This reaction has been studied on both solid NaCl and on aqueous solutions. The uptake of N<sub>2</sub>O<sub>5</sub> on solid NaCl has been studied using Knudsen cells,<sup>3,5</sup> flow reactors,<sup>7,8</sup> annular reactors<sup>10</sup> and diffusion tubes.<sup>6</sup> The reaction has two possible channels if there is water available on the surface: N<sub>2</sub>O<sub>5</sub> + NaCl  $\rightarrow$  ClONO<sub>2</sub> + NaNO<sub>3</sub> (1) and N<sub>2</sub>O<sub>5</sub> + H<sub>2</sub>O/NaCl  $\rightarrow$  2 HNO<sub>3</sub> (2). The presence of the two channels is supported by measured yields of ClONO<sub>2</sub> (relative to N<sub>2</sub>O<sub>5</sub> lost) that vary from 60–100%<sup>3,5,6,8</sup> and by the observation of gaseous HCl as a reaction product.<sup>5</sup> Because hydrolysis on the surface occurs in addition to the reaction with Cl<sup>-</sup>, the net uptake coefficient for N<sub>2</sub>O<sub>5</sub> is particularly sensitive to the presence of surface-adsorbed water (SAW), with higher values for powders where there are more steps and edges that hold SAW. For example, Leu et al.<sup>7</sup> measured an upper limit of  $\gamma < 1.0 \times 10^{-4}$  for salt powders that had been heated overnight in a vacuum, but  $\sim 4.5 \times 10^{-4}$  for samples that were only pumped on for about an hour. Fenter et al.<sup>3</sup> reported a preferred value for the uptake coefficient of  $(5 \pm 2) \times 10^{-4}$ ; however, the measured values varied from  $2 \times 10^{-3}$  for monodisperse powders (after correction for pore diffusion by factors of  $\sim 5$  to 30) to  $< 1.0 \times 10^{-4}$  for a polished window face. Hoffman et al.<sup>5</sup> report a steady state value of  $\gamma_{ss} = 3 \times 10^{-3}$  based on Knudsen cell studies of powders using less than a layer of salt where corrections to the available surface area due to diffusion into the salt are not necessary; the branching ratio for reaction (1) was measured to be  $0.73 \pm 0.28$  ( $2\sigma$ ).  
The uptake of N<sub>2</sub>O<sub>5</sub> on NaCl solutions or aqueous particles has been measured by a number of techniques.<sup>1,2,4,11,14-16</sup> Overall, the reported values of  $\gamma$  for relative humidities between 45 and 100% are between  $1.5 \times 10^{-2}$  to  $5.0 \times 10^{-2}$  and temperatures between 263 K and room temperature. Zetzsch and coworkers<sup>1,2</sup> used an aerosol chamber to measure the uptake of N<sub>2</sub>O<sub>5</sub> on deliquesced NaCl particles from 71–94% RH, and obtained a value of  $\gamma = 3.2 \times 10^{-2}$ . Behnke et al.<sup>1</sup> measured ClONO<sub>2</sub> in a yield of  $66 \pm 7\%$  from aerosol particle experiments. In a wetted wall flow tube, the yield was observed to increase to 100% at concentrations of NaCl of 1 M and above. Thornton and Abbatt<sup>15</sup> report a yield of at least 50% ClONO<sub>2</sub> at 50% RH, using an aerosol flow tube technique. It is proposed by both groups that a mechanism involving a competition between the reaction of NO<sub>2</sub><sup>+</sup> (or H<sub>2</sub>ONO<sub>2</sub><sup>+</sup>) with water to form HNO<sub>3</sub> or with Cl<sup>-</sup> to form ClONO<sub>2</sub> determines the product yield. George et al.<sup>4</sup> used a droplet train and measured the formation of NO<sub>3</sub><sup>-</sup> in the droplets; the value of  $\gamma$  decreased from  $0.039 \pm 0.013$  at 263 K to  $0.014 \pm 0.008$  at 278 K. Stewart et al.<sup>14</sup> measured the uptake of N<sub>2</sub>O<sub>5</sub> on NaCl particles in a flow tube; after correction for diffusion/particle size effects, an uptake coefficient of  $3 \times 10^{-2}$  was derived at relative humidities 30% and

above. Schweitzer et al.<sup>13</sup> used a droplet train apparatus to measure the uptake of  $\text{N}_2\text{O}_5$  on water and on solutions of NaCl, NaBr and NaI with concentrations ranging from 0.1 to 1 M over a temperature range from 262 to 278 K. Within experimental error, all of the uptake coefficients were the same, with an average value of  $\gamma = 0.018 \pm 0.003$ . For 1 M NaCl, the  $\text{ClNO}_2$  yield was 100%.

Note that the uptake kinetics can be suppressed by the presence of an organic monolayer on the aqueous particles.<sup>9,15</sup> Also, the product yield can change to  $\text{Cl}_2$ , when the acidity of the surface is taken below 2 and for chloride concentrations as low as 0.05 M (Roberts et al.<sup>12</sup>).

44.  **$\text{N}_2\text{O}_5 + \text{KBr, NaBr, NaI}$ .** Fenter et al.<sup>1</sup> and Koch et al.<sup>3</sup> measured the uptake coefficient for  $\text{N}_2\text{O}_5$  on KBr at ambient temperature using a Knudsen cell and molecular diffusion tube respectively. The Knudsen cell experiments gave a value of  $(4 \pm 2) \times 10^{-3}$  after correction (by factors of 6–16) for pore diffusion, and the molecular diffusion tube a value of  $(2.5 \pm 1) \times 10^{-3}$ . In the Knudsen cell studies, the uptake coefficient was larger for powders and a depolished window face (both  $4 \times 10^{-3}$ ) than for a polished window face ( $< 1 \times 10^{-4}$ ), similar to the observations for the NaCl reaction ( $\text{N}_2\text{O}_5 + \text{NaCl}$ ); this again suggests the importance

of surface-adsorbed water and possibly surface defects created by roughening (which, however, also hold water) for the reaction. The initial product of the reaction is  $\text{BrNO}_2$ , identified by Finlayson-Pitts et al.<sup>2</sup> by FTIR but this can react further with the salt to generate  $\text{Br}_2$ , the product observed by Fenter et al.<sup>1</sup> Schweitzer et al.<sup>4</sup> used a droplet train apparatus to measure the uptake of  $\text{N}_2\text{O}_5$  on water and on solutions of NaBr and NaI, as well as NaCl, with concentrations ranging from 0.1 to 1 M over a temperature range from 262 to 278 K. Within experimental error, all of the uptake coefficients were the same, with an average value of  $\gamma = 0.018 \pm 0.003$ . For the NaBr reaction, the gas phase products were  $\text{BrNO}_2$ ,  $\text{Br}_2$ , and HONO. For the NaI reaction, the only gas phase product observed was  $\text{I}_2$ .

  - (4) Schweitzer, F.; Mirabel, P.; George, C. Multiphase chemistry of  $\text{N}_2\text{O}_5$ ,  $\text{ClNO}_2$  and  $\text{BrNO}_2$ . *J. Phys. Chem. A* **1998**, *102*, 3942-3952.
- 45.  $\text{N}_2\text{O}_5 + \text{sea salt}$ .** The uptake of  $\text{N}_2\text{O}_5$  on solid synthetic sea salt was measured to be  $\gamma = (3.4 \pm 0.8) \times 10^{-2}$  ( $2\sigma$ ) by Hoffman et al.<sup>1</sup> This will be an upper limit as 1–2 layers of salt were used and no correction was made for diffusion into the bottom layer. However, it is clear that the reaction is at least an order of magnitude faster than that for NaCl; the yield of  $\text{ClNO}_2$  is 100%.  
 Stewart and Cox<sup>3</sup> measured the uptake of  $\text{N}_2\text{O}_5$  on submicron synthetic sea salt aerosols in a flow tube; after correction for diffusion/particle size effects, a value of  $\gamma = 2.5 \times 10^{-2}$  was derived, independent of relative humidity above 30%. Similar results are reported for the same substrate by Thornton and Abbott,<sup>4</sup> with the uptake coefficient changing from 0.02 to 0.03 from 43 to 70% RH. For partially crystallized artificial sea salt, the uptake coefficient was 0.005 at 30% RH.  
 Experiments were conducted by Lopez-Hilfiker et al.<sup>2</sup> in a coated-wall flow tube on the uptake of  $\text{N}_2\text{O}_5$  to frozen salt solutions containing variable ratios of Cl to Br, from temperatures of 258 to about 240 K.  $\text{Br}_2$  and  $\text{ClNO}_2$  products were observed with a total yield of unity, with their ratios dependent upon both temperature and the Cl/Br ratio of the frozen solution.

- 46.  $\text{HONO} + \text{H}_2\text{O(l)}$ .** Bongartz et al.<sup>1</sup> present uptake measurements by two independent techniques, the liquid jet technique of Schurath and co-workers and the droplet train/flow tube technique of Mirabel and co-workers (Ponche et al.<sup>4</sup>). With a surface temperature of ~245 K the droplet train techniques yielded  $0.045 < \gamma < 0.09$ , while the liquid jet operating with a surface temperature of 297 K obtained  $0.03 < \gamma < 0.15$ . Mertes and Wahner<sup>3</sup> used a liquid jet technique to measure  $4 \times 10^{-3} < \gamma < 4 \times 10^{-2}$  at 278 K. Harrison and Collins<sup>2</sup> performed aerosol flow reactor experiments on deliquescent sodium chloride and ammonium sulfate droplets at 279 K obtaining reactive uptake coefficients of  $0.0028 \pm 0.0015$  and  $0.0028 \pm 0.0006$ , for 85% relative humidity conditions, respectively; these measurements are probably subject to significant

surface saturation. Since HONO uptake by liquid water probably involves hydrolysis, an increase in Henry's law solubility with decreasing temperature may be offset by a decreasing hydrolysis rate constant, leaving the uptake coefficient's temperature trend uncertain. Measured uptake coefficients will not correspond to the mass accommodation coefficient.

- 47. HONO + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Zhang et al.<sup>4</sup> measured uptake coefficients for HONO on sulfuric acid that increased from  $(1.6 \pm 0.1) \times 10^{-2}$  for 65.3 wt% H<sub>2</sub>SO<sub>4</sub> (214 K) to  $(9.1 \pm 1.6) \times 10^{-2}$  for 73 wt% H<sub>2</sub>SO<sub>4</sub> (226 K). Fenter and Rossi<sup>3</sup> measured uptake coefficients rising from  $1.8 \times 10^{-4}$  for 55 wt% H<sub>2</sub>SO<sub>4</sub> (220 K) to  $3.1 \times 10^{-1}$  for 95 wt% H<sub>2</sub>SO<sub>4</sub> (220 K and 273 K). Baker et al.<sup>1</sup> measured much smaller uptake coefficients for 60 wt% at 298 K. In general, the values measured by Zhang et al.<sup>4</sup> are a factor of 2 to 5 higher than those of Fenter et al.<sup>3</sup> for comparable acid concentrations. Since the reaction probably depends on both temperature and acid concentration and since the data scatter is high in both experiments, further independent data will be required to define  $\gamma$  as a function of acid concentration and temperature. These data are generally consistent with the effective Henry's law constant measurements of Becker et al.<sup>2</sup> who illustrate that HONO solubility decreases exponentially with H<sub>2</sub>SO<sub>4</sub> concentration until ~53 wt%, at which point reaction to form nitrosyl sulfuric acid increases H\* dramatically as H<sub>2</sub>SO<sub>4</sub> concentration increases. Baker et al.<sup>1</sup> invoke surface decomposition of HONO to explain their room temperature data, since they separately determine that the bulk second-order disproportionation rate for HONO is too slow to account for even their small uptake coefficients. It is possible that surface formation of nitrosyl sulfuric acid and not HONO disproportionation is responsible for much of their measured uptake. The Zhang et al.<sup>4</sup> and Fenter and Rossi<sup>3</sup> data have been combined and fit with a four-term polynomial as a function of acid wt% (these data did not show an obvious temperature dependence):
- $$\ln \gamma = a + b \text{ wt} + c \text{ wt}^2 + d \text{ wt}^3$$
- where wt is the H<sub>2</sub>SO<sub>4</sub> wt%, and
- $$a = -155.7 \pm 29.7$$
- $$b = 5.663 \pm 1.232$$
- $$c = -0.07061 \pm 0.01679$$
- $$d = 0.000297 \pm 0.000076$$
- This parameterization should be used only within the 55–95-wt% H<sub>2</sub>SO<sub>4</sub> range and the 214 to 273 K temperature range.

- 48. HONO + HCl + H<sub>2</sub>O(s).** Knudsen cell uptake studies for HONO/HCl co-deposited on ice (180–200 K) and for HONO on 0.1 to 10 M HCl frozen solutions (~190 K) by Fenter and Rossi<sup>3</sup> showed HONO uptake

coefficients in the 0.02 to 0.12 range as long as surface HCl concentrations significantly exceed HONO concentrations. ClNO was evolved quantitatively with HONO consumption. In a coated wall flow tube Diao and Chu<sup>2</sup> observed orders of magnitude lower uptake coefficients, even though low partial pressures of HONO were used. Some of the HCl partial pressures will have been large enough to melt the ice surface (Abbatt et al.<sup>1</sup>).

- 49. HONO + HCl on H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Fenter and Rossi<sup>1</sup> saw no reaction for acid wt% >65. They measured  $\gamma = 2.0 \pm 0.7 \times 10^{-3}$  for 60 wt% acid saturated with HONO at 230 K. Zhang et al.<sup>3</sup> also measured the uptake of HCl after exposure to HONO, they observed HCl uptake with  $\gamma_s$  between 0.01–0.02 over an acid wt% range of 60.8–71.3 (T = 207.9–222.6 K). The reaction was also studied by Longfellow et al.<sup>2</sup> using both HCl doped and HONO doped sulfuric acid aerosols. Their uptake measurements confirmed reaction at higher acid wt%, but by using lower HONO partial pressures they measured smaller  $\gamma_s$ . The reverse reaction, ClNO hydrolysis, was also studied in a wetted wall flow reactor and in the aerosol flow reactor by Longfellow et al.<sup>2</sup> and in a Knudsen cell reactor by Fenter and Rossi.<sup>1</sup> Data show clear evidence of both surface and bulk kinetics for the forward reaction. Longfellow et al.<sup>2</sup> report  $k^{II}$  values for the bulk reaction (in units of  $10^4 \text{ M}^{-1} \text{ s}^{-1}$ ) for 50 wt%: 81 at 250 K and 15 at 205 K; for 60 wt%: 9.4 at 250 K, 6.9 at 230 K and 5.0 at 219 K; for 67 wt%: 3.9 at 250 K; and for 70 wt%: 5.8 at 269 K and 0.35 at 215 K. The reaction is clearly complex and will require a comprehensive model of both the surface and bulk processes to arrive at an appropriate parameterization for  $\gamma$ .

- 52.  $\text{HONO} + \text{Al}_2\text{O}_3(\text{s})$ .** Romanias et al.<sup>2</sup> used a coated wall flow reactor with solid films of  $\sim 20$  nm  $\gamma$ -alumina particles to measure HONO uptake coefficients over a RH range of  $1.4 \times 10^{-4}$  to  $35.4\%$  and a temperature range of  $274$ – $320$  K, implementing mass spectrometric detection of HONO and its gaseous reaction products NO and  $\text{NO}_2$ .
- The effect of near ultraviolet radiation ( $315$ – $400$  nm,  $J_{\text{NO}_2} = 0.002$ – $0.012 \text{ s}^{-1}$ ) on uptake was also investigated. Reactive uptake was confirmed by a lack of HONO desorption and direct NOx product detection. Measured uptake coefficients are independent of [HONO] and T, but strongly dependent on RH. A moderate UV dependence that increased with RH and was linear in  $J_{\text{NO}_2}$  was observed; neither significantly affected measured product branching ratios of  $(0.40 \pm 0.06)$  for NO and  $(0.60 \pm 0.09)$  for  $\text{NO}_2$ . Uptake coefficients were determined as a function of RH without and with UV radiation ( $J_{\text{NO}_2} \sim 0.012 \text{ s}^{-1}$ ). The results were parameterized (estimated uncertainty of  $\pm 30\%$ ):
- $$\gamma(\text{dark}) = 4.8 \times 10^{-6} (\text{RH})^{-0.61} \quad (\text{RH} = 1.4 \times 10^{-4} \text{ to } 10.5\%)$$
- $$\gamma(\text{UV}) = 1.7 \times 10^{-5} (\text{RH})^{-0.44} \quad (\text{RH} = 1.4 \times 10^{-4} \text{ to } 35.4\%)$$
- The same authors published similar results for HONO reactive uptake on  $\text{Fe}_2\text{O}_3$  and Arizona Test Dust.<sup>1</sup> Given results from only one laboratory and no information on  $\alpha$ -alumina surfaces, no uptake coefficient values are recommended.

- 53.  $\text{HNO}_3 + \text{NaCl(s)}$  and  $\text{NaCl(aq)}$ .** Recommendation is based on an average of the values of Hoffman et al.,<sup>8</sup> Ghosal and Hemminger,<sup>6</sup> the data of Davies and Cox<sup>3</sup> as revised by Ghosal and Hemminger<sup>6</sup> using their model for surface reactivation, and the single crystal data of Leu et al.<sup>12</sup> Hoffman et al.<sup>8</sup> used less than a single layer of particles so that diffusion into the underlying layers is not a factor to obtain an initial value of  $\gamma_0 = (2.3 \pm 1.9) \times 10^{-3}$  ( $2\sigma$ ). This is consistent within the combined experimental errors with a value of  $(1.3 \pm 0.6) \times 10^{-3}$  determined from the formation of nitrate on the surface of single crystal (100)  $\text{NaCl}$  by Ghosal and Hemminger,<sup>6</sup> and with a value of  $1.1 \times 10^{-3}$  from application of the Ghosal and Hemminger model to the Davis and Cox data.<sup>3</sup> Ghosal and Hemminger suggest that the value could be as high as  $5 \times 10^{-3}$  for  $\text{NaCl}$  powders that have more steps and edges that hold SAW.<sup>7</sup> At longer reaction times, the steady-state value<sup>8</sup> is a factor of two smaller,  $\gamma = 1 \times 10^{-3}$ . The reaction is hypothesized to occur both on dry terraces, which saturate rapidly, and on steps and edges that hold surface-adsorbed water. The water acts to recrystallize the product  $\text{NaNO}_3$  so that the surface does not passivate during the reaction at atmospherically relevant  $\text{HNO}_3$  pressures. This model, developed and modified by several research groups<sup>2,3,6,8</sup> brings together most of the seemingly disparate measurements of the reaction probability made using a variety of techniques including flow tubes,<sup>3</sup> Knudsen cells,<sup>2,4,5,8</sup> and XPS studies of nitrate formation on single crystals.<sup>6,7,17</sup> The only gas phase product observed is  $\text{HCl}$ , with a yield that is within experimental error of 100%. The higher value of  $(1.3 \pm 0.4) \times 10^{-2}$  of Leu et al.<sup>12</sup> was obtained by correcting even larger measured values using a pore diffusion model;<sup>9,10</sup> the corrections were typically in the range of a factor of 4–6. On single crystal  $\text{NaCl}$  where such corrections were not necessary, Leu et al.<sup>12</sup> measured a value of  $(2.4 \pm 0.6) \times 10^{-3}$ . A value of  $(4 \pm 1) \times 10^{-2}$  was measured using a molecular diffusion tube technique by Koch et al.<sup>11</sup> The corrected value of  $(8.7 \pm 1.4) \times 10^{-5}$  reported by Zangmeister and Pemberton<sup>18,19</sup> using Raman spectroscopy to follow the nitrate formed on the surface is lower than the other values likely because a much higher  $\text{HNO}_3$  concentration was used ( $\sim 10^{18} \text{ cm}^{-3}$ ), which would lead to a

larger coverage of the surface by the recrystallized NaNO<sub>3</sub> product and passivation of much of the NaCl surface.

Abbatt and Waschewsky<sup>1</sup> measured the loss of gas-phase HNO<sub>3</sub> in a flow tube containing deliquesced 1–5 μm NaCl particles (75% RH) and obtained a lower limit to the uptake coefficient for HNO<sub>3</sub> of 0.2 on unbuffered NaCl. Stemmler et al.<sup>15</sup> report a value of 0.5 ± 0.2 for the initial uptake coefficient on deliquesced particles at 60% RH. Tolocka et al.<sup>16</sup> followed the reaction of HNO<sub>3</sub> with 100–220 nm NaCl particles at 80% RH using single particle MS to measure the Cl<sup>-</sup>/NO<sub>3</sub><sup>-</sup> ratio; the uptake coefficient for 100 nm particles was (4.9 ± 2.7) × 10<sup>-3</sup> and increased with droplet size. Saul et al.<sup>14</sup> have extended the Tolocka et al. work, by studying the reaction over a wide range of relative humidities, both above and below the efflorescence point. Uptake coefficients on the mixed nitrate-chloride particles reach a maximum of 0.12 or so at 50% RH, decreasing at both higher and lower RHs. The presence of hygroscopic MgCl<sub>2</sub> increases the uptake coefficient at low RHs, where the particles may remain liquid. Liu et al.<sup>13</sup> using static particles probed spectroscopically determine the maximum uptake coefficients to be 0.2 (uncertainty a factor of three), also close to 50% RH, decreasing at higher and lower RHs. The combination of these studies shows that the initial uptake of HNO<sub>3</sub> into solution is fast, with  $\gamma_0 > 0.2$ ; as the solution becomes acidified, HCl is expelled as the gaseous product. The uptake coefficient may decrease when the reaction proceeds on processed particles, where a large amount of nitrate has built up. In such cases, the maximum reactivity is at close to 50% RH. Note that the Stemmler et al.<sup>15</sup> study illustrated that monolayer coverages of long-chain surfactants can reduce the initial uptake coefficient by over an order of magnitude.

- 54.  $\text{HNO}_3 + \text{NaBr}$  and  $\text{KBr}$ .** Fenter et al.<sup>1</sup> reported that the value of  $\gamma$  for uptake of  $\text{HNO}_3$  on  $\text{NaCl}$ ,  $\text{NaBr}$ ,  $\text{KBr}$  and  $\text{KCl}$  was the same,  $(2.8 \pm 0.3) \times 10^{-2}$ , independent of sample mass. Koch et al.<sup>2</sup> reported an uptake coefficient of  $\text{HNO}_3$  on  $\text{KBr}$  of  $(2 \pm 1) \times 10^{-2}$  using a molecular diffusion tube technique. As discussed in Note 7, integration of the results of an extensive series of studies in different laboratories using different techniques, uptake coefficients for  $\text{HNO}_3$  on  $\text{NaCl}$  give a value for the  $\text{HNO}_3\text{-NaCl}$  reaction that is smaller than measured in the Fenter et al.<sup>1</sup> and Koch et al.<sup>2</sup> studies. These values for  $\text{KBr}$  may therefore be upper limits. Leu et al.<sup>3</sup> reported a value that is an order of magnitude smaller,  $(2.8 \pm 0.5) \times 10^{-3}$  after applying large corrections (about an order of magnitude) for pore diffusion; the average uncorrected value using the geometric area was 0.027.

- (3) Leu, M.-T.; Timonen, R. S.; Keyser, L. F. Kinetics of the heterogeneous reaction  $\text{HNO}_3(\text{g}) + \text{NaBr}(\text{s}) \rightarrow \text{HBr}(\text{g}) + \text{NaNO}_3(\text{s})$ . *J. Phys. Chem. A* **1997**, *101*, 278-282.
- 55.  $\text{HNO}_3 + \text{sea salt}$ .** The uptake coefficient for  $\text{HNO}_3$  on synthetic sea salt<sup>1</sup> is much larger than that on  $\text{NaCl}$ , which is attributed to the very hygroscopic nature of sea salt due to such components as the magnesium chloride and its hydrates (see Note on  $\text{O}_3 + \text{sea salt}$ ). De Haan and Finlayson-Pitts<sup>1</sup> reported initial uptake coefficients of  $\gamma_0$  in the range of 0.07 to 0.75 and steady state values in the range of 0.03 to 0.25; these were measured using salt layers from 2 layers to  $10^3$  layers. The initial uptake coefficient on  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$  was  $\geq 0.4$  and the steady-state value  $> 0.1$ . At these high uptake values, the correction for diffusion into underlying layers is expected to be small. The large uptake coefficient on sea salt is consistent with the values measured for uptake on concentrated aqueous solutions of  $\text{NaCl}$  and the high water content of the surface of sea salt (see  $\text{O}_3 + \text{seasalt}$  Note above). The yield of  $\text{HCl}$  was within experimental error of 100%. Guimbaud et al.<sup>2</sup> measured the uptake coefficient of  $\text{HNO}_3$  on 70 nm supersaturated sea-salt particles (deliquesced particles held at 55% RH) to be  $0.50 \pm 0.20$ ; they concluded that this was the mass accommodation coefficient.

- 56.  $\text{HNO}_3 + \text{Al}_2\text{O}_3$ .** Börnsen et al.<sup>1</sup> used diffuse reflectance FTIR observations to show that  $\text{HNO}_3$  reacts with surface hydroxyl groups on  $\gamma$ -alumina at 299 K to produce surface bonded nitrate, while Goodman et al. reported similar observations for  $\alpha$ -alumina at 296 K.<sup>2</sup> Goodman et al.<sup>2</sup> also observed that higher relative humidity lead to higher  $\text{HNO}_3$  uptake. They integrated their nitrate absorbance feature to yield a time averaged uptake coefficient of  $(4 \pm 1) \times 10^{-8}$ .<sup>2</sup> Underwood et al.<sup>5</sup> report a linear mass dependent, BET corrected  $\gamma_0$  for  $\alpha$ -alumina at 295 K of  $(9.7 \pm 0.5) \times 10^{-5}$ . Hanisch and Crowley also measured liner mass

dependent  $\gamma_0$ s on  $\alpha$ -alumina (at 298 K) for four particle sizes, which yielded an average value of  $0.133 \pm 0.033$ .<sup>3</sup> They argue that the lack of variance of  $\gamma_0$ s on a large range of particle sizes and masses indicate that the BET correction to the geometrical surface area is not required. They also measured  $\gamma_0$  for an unpolished single crystal of  $(1.6 \pm 1.4) \times 10^{-3}$  and smaller values on polished single crystals, showing the higher density of surface defect sites on small amorphous particle are critical for their high reactive active uptake coefficients. The recommendation is based on the Hanisch and Crowley data and analyses for particulate samples.<sup>3</sup> Seisel et al.,<sup>4</sup> used Knudsen cell uptake experiments at 298 K to measure an initial uptake ( $\gamma_0$ ) value of  $0.13 \pm 0.02$  for  $\gamma$ -alumina with  $\text{HNO}_3$  vapor concentrations of  $\sim 10^{11} \text{ cm}^{-3}$ . Lower values of  $\gamma$  were observed for higher nitric acid partial pressures; water vapor was observed as a product. They also performed DRIFTS experiments that yielded a mean uptake coefficient for surface nitrate formation of  $(7.7 \pm 0.8) \times 10^{-3}$  at 298 K.

- 58.  $\text{NH}_3 + \text{H}_2\text{SO}_4 \bullet n\text{H}_2\text{O}$ .** Robbins and Cadle,<sup>6</sup> Huntzicker et al.,<sup>4</sup> McMurry et al.,<sup>5</sup> and Daumer et al.<sup>1</sup> all studied  $\text{NH}_3$  uptake by sulfuric acid aerosols in near room temperature flow reactors ( $T = 281$ – $300$  K). Uptake coefficients varied between 0.1 and 0.5. Rubel and Gentry<sup>7</sup> used levitated  $\text{H}_3\text{PO}_4$  acid droplets to show that heterogeneous reaction does control the initial  $\text{NH}_3$  uptake on strong acid solutions. Both Rubel and Gentry and Däumer et al. also explored the effect of organic surface coatings. Swartz et al.<sup>8</sup> used a droplet train flow reactor to measure reactive uptake coefficients on 20 to 70 wt% acid over a temperature range from 248 to 288 K. Measured uptake coefficients varied from 1.0 at 55 wt% and above to 0.3 at 20 wt% and drop off smoothly to the pure water results reported by the same group, as well as other droplet train flow reactor and coaxial jet uptake studies.<sup>9</sup> Hanson and Kosciuch<sup>2</sup> used an aerosol flow reactor to measure reactive uptake coefficients at room temperature (287 to 297 K) from 15 to 65 wt%. While the data have a fair amount of scatter, taken as a whole they are consistent with  $\gamma = 1$  over the whole range of acid concentrations. There is no obvious reason for the discrepancy between the 15 to ~45 wt% results from Swartz et al.<sup>8</sup> and Hanson and Kosciuch,<sup>2</sup> the two groups have discussed conceivable issues at length in print<sup>9</sup> and Hanson and Kosciuch.<sup>3</sup>

CO<sub>2</sub> + Al<sub>2</sub>O<sub>3</sub>(s).** Parkyns<sup>1</sup> and Szanyi and Kwak<sup>2</sup> each report FTIR studies of CO<sub>2</sub> chemisorbed on  $\gamma$ -alumina surfaces annealed at temperatures up to ~800 K. They report that CO<sub>2</sub> can react with the HO-Al surface sites of  $\gamma$ -alumina at room temperature to form adsorbed bicarbonate structures. They also show that the surface OH on  $\gamma$ -alumina can be eliminated by calcination of the alumina surfaces at temperatures near 800 K. Adsorbed CO<sub>2</sub> on the dehydroxylated  $\gamma$ -alumina forms weakly bound carbonate species. No kinetic uptake data are available for CO<sub>2</sub> uptake.

- 60. H<sub>2</sub>CO + Al<sub>2</sub>O<sub>3</sub>(s).** Carlos-Cueller et al.<sup>1</sup> reported Knudsen cell studies that determined  $\gamma_0$  values for oxygenated volatile organic compounds (VOCs) at 295 K. They measured a  $\gamma_0$  on  $\alpha$ -alumina for formaldehyde of  $(7.7 \pm 0.3) \times 10^{-5}$ , based on BET surface areas and the KML<sup>2</sup> correction for porosity; relatively “sticky” formaldehyde may not access the full BET surface and thus  $\gamma_0$  may be underestimated. Xu et al.<sup>3</sup> used a DRIFTS Reactor with  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> surfaces over a temperature range of 84–573 K and a RH range of 0–80%. BET and geometric surface areas were used to calculate initial uptake coefficients. Formaldehyde uptake was independent of gas phase O<sub>2</sub> over the studied range ( $0.18\text{--}730 \times 10^{13} \text{ cm}^{-3}$ ); uptake was negatively correlated with RH. Surface analyses included FTIR, X-ray Diffraction and SEM. The initial surface product is dioxymethylene that is oxidized to formate, with reaction order of  $0.74 \pm 0.05$ . Polyoxymethylene is a secondary adsorbed product. Reactive uptake saturates active surface sites so initial  $\gamma_0$  values are reported for both geometric and BET surface areas. For T = 298 K,  $\gamma_0(\text{Geo}) = (3.6 \pm 0.8) \times 10^{-4}$  and  $\gamma_0(\text{BET}) = (1.4 \pm 0.31) \times 10^{-8}$  (T = 298 K, RH = 0);  $\gamma_0(\text{BET}, 298 \text{ K})$  decreases approximately a factor of 2 as RH increases from 0 to 80%;  $\gamma_0(\text{BET}, 0 \text{ RH})$  increases irregularly by approximately a factor of 3 as T increases from 273 to 373 K. The Xu et al. room temperature BET value for  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> is ~5000 lower than the Carlos-Cueller et al. value for  $\alpha$ -alumina. It is unclear how much of this is due to systematic error in one or both experiments and how much is due to different surface properties for the two alumina phases. Given the available data an upper limit of  $\gamma_0 < 5 \times 10^{-4}$  over the temperature range of 270–300 K is estimated for both phases.

- 61.  $\text{CH}_3\text{OH} + \text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O(l)} \text{ and } \text{H}_2\text{SO}_4 \cdot m\text{HNO}_3 \cdot n\text{H}_2\text{O(l)}$ .** Van Loon and Allen<sup>2</sup> report spectroscopic observations at 293 K for 0 to 96.5 wt%  $\text{H}_2\text{SO}_4$  exposed to methanol vapor. They observed rapid surface adsorption and saturation, followed by slower bulk absorption. For acid concentrations between 47.1 and 63.3 wt% they observed surface reaction between methanol and sulfuric acid that formed methyl hydrogen sulfate,  $\text{CH}_3\text{SO}_4\text{H}$ . Iraci et al.<sup>1</sup> used infrared spectroscopy to monitor the production of gas phase methyl nitrate,  $\text{CH}_3\text{ONO}_2$ , from the bulk reaction of ternary sulfuric acid/nitric acid/water solutions with 0.00005–0.005 M  $\text{CH}_3\text{OH}$  in 50.5 to 63.6 wt%  $\text{H}_2\text{SO}_4$  with 0.03–0.21 M  $\text{HNO}_3$  between 278.2 and 328.6 K. Within this range methyl nitrate production increased linearly with methanol and nitric acid concentration and exponentially with sulfuric acid concentration. At high acid concentrations nitric acid reacts with protons to form water and the nitronium ion,  $\text{NO}_2^+$ ; methyl nitrate production was observed to be proportional to the  $\text{NO}_2^+$  concentration indicating it was the nitrating agent.

- 63.  $\text{HC(O)OH} + \text{Al}_2\text{O}_3(\text{s})$ .** Tong and co-workers<sup>3,4</sup> used a DRIFTS reactor to investigate the uptake of formic acid on beds of  $\alpha\text{-Al}_2\text{O}_3$  particles; surface areas were estimated with BET measurements as well by geometric sample area. Their initial study<sup>3</sup> reported  $\gamma(\text{BET})$  and  $\gamma(\text{Geo})$  for formic, acetic and propionic acids on  $\alpha\text{-Al}_2\text{O}_3$  at 300 K over a RH range (0–90%). For RH(0) they reported:

Acid	$\gamma(\text{BET})$	$\gamma(\text{Geo})$
$\text{HC(O)OH}$	$(2.37 \pm 0.30) \times 10^{-7}$	$(2.07 \pm 0.26) \times 10^{-3}$
$\text{CH}_3\text{C(O)OH}$	$(5.99 \pm 0.78) \times 10^{-7}$	$(5.00 \pm 0.69) \times 10^{-3}$
$\text{CH}_3\text{CH}_2\text{C(O)OH}$	$(3.03 \pm 0.52) \times 10^{-7}$	$(3.04 \pm 0.63) \times 10^{-3}$

It is likely that  $\gamma(\text{BET})$  underestimates the true uptake coefficient since organic acids adsorb and react before penetrating some pores and that  $\gamma(\text{Geo})$  overestimates uptake rates. The effect of relative humidity on the  $\text{HC(O)OH}$  uptake coefficients is modest, with a slight (~10%) rise between RH(0) and RH(20%) and then a gradual fall off (~33%) between RH(20%) and RH(95%). A second publication by Tong and co-workers<sup>4</sup> focused on the effects of temperature on uptake rate. For RH(0) they measured a modest increase (less than a factor of two) as T decreases from 298 to 240 K:

T (K)	$\gamma(\text{BET})$	$\gamma(\text{Geo})$
298	$(1.34 \pm 0.02) \times 10^{-6}$	$(2.35 \pm 0.03) \times 10^{-3}$
285	$(1.52 \pm 0.04) \times 10^{-6}$	$(2.65 \pm 0.07) \times 10^{-3}$
277	$(1.70 \pm 0.03) \times 10^{-6}$	$(2.98 \pm 0.03) \times 10^{-3}$
273	$(1.77 \pm 0.01) \times 10^{-6}$	$(3.09 \pm 0.03) \times 10^{-3}$
263	$(1.96 \pm 0.02) \times 10^{-6}$	$(3.43 \pm 0.04) \times 10^{-3}$
250	$(2.22 \pm 0.02) \times 10^{-6}$	$(3.89 \pm 0.03) \times 10^{-3}$

Note that their earlier  $\gamma$ (Geo) for room temperature and RH(0) of  $(2.07 \pm 0.26) \times 10^{-3}$ <sup>3</sup> is in good agreement with the value of  $(2.35 \pm 0.03) \times 10^{-3}$  reported in Wu et al.,<sup>4</sup> however, their later room temperature  $\gamma$ (BET) value is more than a factor of five larger than their earlier value, calling into question the reliability of BET surface area determinations. Infrared spectra indicated surface enhanced crystallization of HCOOH at lower temperatures as well reaction with surface hydroxyl groups to form formate. Based on these data only an upper limit of  $\gamma_0 < 0.01$  is recommended for  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>.

Rubasinghege et al.<sup>2</sup> used a Quartz Crystal Microbalance (QCM) and Attenuated Total Reflectance FTIR (ATR-FTIR) to characterize total HC(O)OH uptake and surface reactions on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub> and kaolinite surfaces at T (298 K) and RH (<1%); no kinetic data was presented. They observed both reversible and irreversible adsorption of HC(O)OH on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub>. Adsorbed water, controlled by RH, increases the irreversible uptake of HC(O)OH. The resulting layer of adsorbed formate decreases the surface hydrophilicity, decreasing the amount of water uptake. Raun et al.<sup>1</sup> report a density functional simulation of HC(O)OH interacting with an  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> (0001) surface, presenting adsorbate dissociation pathways and estimating the energy barrier for dehydration reactions.

- 64. CH<sub>3</sub>CH<sub>2</sub>OH + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** Timonen and Leu<sup>2</sup> used a trough flow reactor to measure uptake coefficients for ethanol on 41.1 to 79.3 wt% H<sub>2</sub>SO<sub>4</sub>, for selected temperatures between 193 to 273 K, but primarily for temperatures from 203 to 258 K. Uptake coefficients for 70.3–79.3 wt% acid showed little temperature variation, starting at ~0.07 for 203 K and falling to 0.05 to 0.06 above 250 K, while uptake coefficients for 41.1 to 64.1 wt% started at ~0.07 at 203 K and decreased to about 0.02 at 233 K for 41.1 wt%, to ~0.03 at 243 K for 54.4 wt% and ~0.035 at 253 K for 64.1 wt%. Uptake was only partially reversible, so it was attributed to both physical and reactive processes, making the reported uptake coefficients as upper limits for  $\gamma$ . The authors attributed the reactive portion of the uptake to esterification reactions, forming ethyl hydrogen sulfate and diethyl sulfate, and saw some mass spectral evidence for these products when they mixed ethanol with 80 wt% acid in their reactor at 296 K. Michelsen et al.<sup>1</sup> found no evidence for ethyl hydrogen sulfate in Knudsen cell ethanol uptake experiments for 39–76 wt% H<sub>2</sub>SO<sub>4</sub> over a 209–237K temperature range, so the extent of reaction for low temperature acid solutions remains uncertain. Timonen and Leu suggest that at low ethanol vapor fluxes surface reactivity may be important.

- 66. CH<sub>3</sub>CHO + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** Knudsen cell uptake measurements are reported by Michelsen et al.<sup>3</sup> for 38.5–76.2 wt% H<sub>2</sub>SO<sub>4</sub> over a temperature range of 211–241 K, with evidence of reactive uptake for some temperatures in the 38.5–66.3 wt% H<sub>2</sub>SO<sub>4</sub> range. Using a rotating wetted-wall flow reactor Esteve and Nozière<sup>2</sup> measured small, probably solubility constrained, uptake coefficients at 298 ± 3 K for 96 wt% and 89.4 wt% of 9.4 × 10<sup>-6</sup> and 4.2 × 10<sup>-7</sup>, respectively. Michelsen et al. found uptake over the 211–241 K temperature range was controlled by Henry's law solubility, and had a complex dependence on acid concentration due to competition among the reversible bulk phase processes of physical dissolution, hydration to form the gem diol, protonation and enolization, all of which affect H\*. They also saw evidence for aldol condensation at some temperatures for acid concentrations of 66.3 wt% and below. Drawing on the complex aldol condensation mechanism presented to explain the bulk kinetic studies of Baigrie et al.,<sup>1</sup> Michelsen et al. present plausible arguments why non-reversible condensation reactions might have the complex dependence on acid concentrations and temperature that they observed. Given its relatively small rate constant, they suggest that aldol condensation bulk reactions will play a negligible role for typical aldehyde concentrations in the atmosphere.

- 70. H<sub>2</sub>C=C(CH<sub>3</sub>)CHO and H<sub>2</sub>C=CHC(O)CH<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub>(s).** Zhao et al.<sup>1</sup> report a coated wall flow reactor study with Transmission FTIR measurements of adsorption and reaction of both methacrolein (MAC) and methyl vinyl ketone (MVK) on  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> at T~300 K and relative humidity values of RH < 1%, 20% and 60%. They reported RH = 0  $\gamma_0$  values based on BET surface areas of:  $\gamma_0(\text{MAC}) = (2.0 \pm 0.5) \times 10^{-8}$  and  $\gamma_0(\text{MVK}) = (3.8 \pm 0.8) \times 10^{-8}$ . They measured significantly lower  $\gamma_0$ s for RH = 20 and 60% indicating that water vapor blocks reactive surface sites. Major products (>0.03) were CH<sub>3</sub>CH<sub>2</sub>CHO, HCHO ad HCOOH for MAC and isomerization of MVK to CH<sub>3</sub>CH=CHCHO (crotonaldehyde) that then reacted to produce CHOCHO, CH<sub>3</sub>CHO and CH<sub>3</sub>C(O)OH. For molecules this large some BET surface area may not be accessible and derived  $\gamma_0$ s may be underestimated. Given the strong impact of relative humidity and uncertainty in effective surface area no recommendations for  $\gamma_0$ s are made.

- 71. CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> + HCl, Cl, ClO, and OCIO on H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Zhang and Leu<sup>1</sup> performed wetted wall flow reactor studies with Cl species partial pressures in the  $10^{-6}$  to  $10^{-7}$  Torr range and CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> at  $3 \times 10^{-6}$  Torr after equilibrating the acid surfaces (42, 51, and 69 wt% at 202 and 224 K) with CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub>. Also uptake studies with  $5 \times 10^{-7}$  Torr CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> were performed after exposing the acid surface to the Cl species. No Cl species or CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> uptake enhancements were observed under either condition and an upper limit for the reactive uptake coefficient of  $\gamma < 1 \times 10^{-4}$  of CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> was deduced. No gas phase reaction products were observed using CIMS after 42 wt% H<sub>2</sub>SO<sub>4</sub> at 210 K was exposed to CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> and each Cl species for 20 minutes.

- 73. Cl + NaCl(s).** Ciuraru et al.<sup>1</sup> have measured the uptake coefficients for Cl atoms onto pure NaCl and artificial sea-salt in a coated-wall flow tube. The surface area of the substrates is not easily estimated. Uptake coefficients are on the order of  $10^{-2}$  for dry NaCl, with evidence for Cl<sub>2</sub> as a reaction product probably arising from surface recombination.

- (2) Mochida, M.; Akimoto, H.; van den Bergh, H.; Rossi, M. J. Heterogeneous kinetics of the uptake of HOBr on solid alkali metal halides at ambient temperature. *J. Phys. Chem. A* **1998**, *102*, 4819-4828.
- 76. Cl<sub>2</sub> + NaBr and NaI.** Mochida et al.<sup>5</sup> used salt powders and spray-deposited films to obtain a value for the initial uptake coefficient of  $2 \times 10^{-2}$ . The measured uptake coefficients for the salt powders were a factor of six larger, but application of the pore diffusion model of Keyser et al.<sup>3,4</sup> gave this value, which is in agreement with that for a spray-deposited film. Br<sub>2</sub> was generated in a yield of 100%, within experimental error.
- Hu et al.<sup>1</sup> measured the uptake of Cl<sub>2</sub> on aqueous solutions of NaBr and NaI over the temperature range of 263–293 K using a droplet train flow reactor. Measured values of the uptake coefficients on NaBr solutions ranged from 0.16 at 263 K to 0.05 at 293 K, and there was evidence of a surface reaction between Cl<sub>2</sub> and Br<sup>-</sup> at the air-particle interface. Similarly, the uptake coefficients for Cl<sub>2</sub> on NaI solutions ranged from 0.20 to 0.07 over the same temperature range, again with evidence for a contribution from an interface reaction. Huff and Abbatt<sup>2</sup> have studied the reaction of Cl<sub>2</sub> with films formed by freezing NaBr solutions at 233 K, observing Br<sub>2</sub> as the reaction product and that the maximum reaction probability is 0.1 when the surface is saturated with bromide ions.

- 77. Cl<sub>2</sub> + KBr.** Mochida et al.<sup>2</sup> used salt powders and spray-deposited films to obtain a value for the initial uptake coefficients. The value measured for salt powders was 0.176, but after correction for pore diffusion, this became  $3.7 \times 10^{-2}$ , similar to a value of  $2.3 \times 10^{-2}$  measured for spray-deposited films. Br<sub>2</sub> was generated in a yield of 100%, within experimental error. Aguzzi and Rossi<sup>1</sup> measured a similar value,  $2.7 \times 10^{-2}$ , using a Knudsen cell. Santschi and Rossi<sup>3</sup> reported an initial value of  $\gamma_0 = 0.11$  for the uptake of Cl<sub>2</sub> on thin spray-deposited films of KBr that had not been extensively pumped on; this initial value was  $4 \times 10^{-2}$  for films that had been pumped on for hours. They attributed the difference to the removal of surface-adsorbed water (SAW) by extensive pumping.

- 78. Cl<sub>2</sub> + sea salt.** Mochida et al.<sup>1</sup> used a synthetic sea salt and a "natural" seasoning sea salt in Knudsen cell studies of the uptake of Cl<sub>2</sub>. The synthetic sea salt value of  $(2.2 \pm 0.3) \times 10^{-2}$  is the value reported after correction of the measured value of 0.138 using the pore diffusion model. For the "natural" seasoning salt, the measured value was 0.11 which after correction for diffusion into the underlying layers became  $(3.1 \pm 1.1) \times 10^{-2}$ . Br<sub>2</sub> was the major gas phase product, with small mass spectrometric signals also seen for BrCl.

- 79. ClO + H<sub>2</sub>O(s) and HNO<sub>3</sub>•nH<sub>2</sub>O(s).** Proposed reaction (Leu<sup>3</sup>) is  $2 \text{ ClO} \rightarrow \text{Cl}_2 + \text{O}_2$ ; reactive uptake may depend on ClO surface coverage, which in turn may depend on gas phase ClO concentrations. Kenner et al.<sup>2</sup> measured reaction probabilities of  $(8 \pm 2) \times 10^{-5}$  for ice at 183 K which is far lower than the limit of  $>1 \times 10^{-3}$  obtained by Leu.<sup>3</sup> Abbatt,<sup>1</sup> using nearly the same low levels of ClO as Kenner et al., obtained  $\gamma < 1 \times 10^{-5}$  at 213 K. The difference may lie in the level of ClO or other adsorbable reactive species present. The lower value of Abbatt is probably closer to the expected reactivity under stratospheric conditions. Using high concentrations of ClO radicals ( $>10^{12}$  molecules/cm<sup>3</sup>) exposed to ice surfaces at 225 K, McKeachie et al.<sup>4</sup> infer an uptake coefficient of 0.001, which increases with ClO exposure. Formation of higher chlorine oxides, notably OCLO, is observed mass spectrometrically and by UV-VIS spectroscopy, upon warming the ice. It is likely that the high ClO concentrations drive self-reactions on the ice surface. Kenner et al. also measured a reaction probability limit of  $< (8 \pm 4) \times 10^{-5}$  for NAT at 183 K.

- 81. HCl +  $\text{HNO}_3 \cdot m\text{HNO}_3 \cdot n\text{H}_2\text{O(l)}$ .** Two studies have noted HCl activation in concentrated ternary  $\text{H}_2\text{SO}_4/\text{HNO}_3/\text{H}_2\text{O}$  solutions or ice slurries. Luick et al.<sup>2</sup> saw only gas phase HCl in 64.6 wt%  $\text{H}_2\text{SO}_4/4.8$  wt%  $\text{HNO}_3$  at 200 K, but saw a vapor phase Cl partitioning of 50% HCl and 50%  $\text{ClNO}/\text{ClNO}_2$  for a 76.6/20.1 wt% solution (an ice slurry) at 200 K. Cappa et al.<sup>1</sup> saw substantial yields of  $\text{ClNO}$ ,  $\text{ClNO}_2$ , and  $\text{Cl}_2$  at 273 K for a range of solution compositions; e.g. 32.6%, 9.8%, and 44.4% respectively for a total HCl conversion of 86.9% in a 35%  $\text{H}_2\text{SO}_4/45\%$   $\text{HNO}_3$  solution and 20.2%, 6.9%, 27.9% for a 60/25 wt% solution. While no kinetic coefficients or detailed mechanisms are available, these studies do show the potential for HCl activation in strong  $\text{H}_2\text{SO}_4/\text{HNO}_3/\text{H}_2\text{O}$  solutions.

- 82. HOCl + HCl +  $\text{H}_2\text{O(s)}$  and  $\text{HNO}_3 \cdot 3\text{H}_2\text{O(s)}$ .** Hanson and Ravishankara<sup>5</sup> and Abbott and Molina<sup>1</sup> have investigated the HOCl + HCl reaction on water ice and NAT-like surfaces, and Chu et al.<sup>3,4</sup> studied the reaction on water ice. Product yield measurements support the identification of  $\text{Cl}_2$  and  $\text{H}_2\text{O}$  as the sole products. The measured yield of product  $\text{Cl}_2$  is  $0.87 \pm 0.20$  and was stated to be similar on both surfaces according to Abbott and Molina. Within the accuracy of the experiments, the reaction probability does not depend on the gas phase HCl and HOCl densities. Only Abbott and Molina investigated at more than one temperature, their data indicates that  $\gamma$  increases at lower temperatures. A plot of data from the three studies does show a weak temperature trend, with  $\gamma$  increasing about a factor of two as the temperature drops from 202 to 188 K. However, the data are too sparse to assign a definitive temperature dependence. The average of all three studies yields  $\gamma = 0.26 \pm 0.08$  for data based on the geometrical area of the flow tube surfaces. Chu et al.<sup>3</sup> indicate that a porosity correction for their data would reduce their value by a factor of 3 to 4. The real uncertainty would appear to be dominated by systematic uncertainties in porosity corrections and a potential temperature dependence. Given the fact that any porosity correction must reduce the value, a central value of 0.2 is adopted with an uncertainty factor of 2. The high reaction probabilities measured for water ice indicate that this reaction may play a significant role in release of reactive chlorine from the HCl reservoir.
- Two studies (Hanson and Ravishankara<sup>5</sup> and Abbott and Molina<sup>1</sup>) have measured the reaction probability of HOCl + HCl on NAT surfaces. These data show  $\gamma$  increases as the ambient water pressure increases and then reaches a plateau. At relatively high water pressure, the two studies averaged  $\gamma = 0.135 \pm 0.049$ , with no porosity correction. The reaction probability on water-poor NAT-like surfaces falls off dramatically (a factor of 10). A recommendation of 0.1 with an uncertainty factor of 2 is shown in Table 5-2. Carslaw and Peter<sup>2</sup> have published a model of this reaction and its dependence on HCl uptake.

- 83. HOCl + HCl + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** This process has been studied in coated flow tubes over ~200–260 K by Zhang et al.,<sup>7</sup> Hanson and Ravishankara,<sup>3</sup> Donaldson et al.,<sup>1</sup> and Hanson and Lovejoy.<sup>2</sup> Hanson and Lovejoy also made measurements in an aerosol flow tube from 251 to 276 K. A model of this and related sulfuric acid aerosol reactions tailored to stratospheric conditions has been published by Hanson et al.<sup>4</sup> Zhang et al. held the water vapor partial pressure at  $3.8 \times 10^{-4}$  Torr and showed  $\gamma$  increased by a factor of 50 as the temperature was lowered from 209 to 198 K increasing the water mole fraction, showing that the reaction rate is strongly dependent on water activity. A detailed kinetic uptake model has been developed to fit the experimental data.<sup>6</sup> The formulation for  $\gamma$  is given as:

$$\frac{1}{\gamma} = \frac{1}{\alpha} + \frac{1}{\Gamma_{HOCl}^{rxn}}$$

where

$$\Gamma_{HOCl}^{rxn} = \frac{4H_{HOCl}RT}{\bar{c}} (D_{HOCl}k_{HOCl-HCl})^{1/2}$$

At the low temperatures of interest,  $\alpha$  for HOCl was assumed to be unity consistent with the value for HCl measured at 240 K and below (Robinson et al.<sup>5</sup>). The individual formulations for  $H_{HOCl}$ ,  $D_{HOCl}$  and  $k_{HOCl-HCl}$  are given in Table A-4 in Shi et al.<sup>6</sup> Reaction of HOCl with HCl is considered to be acid catalyzed. It is known that the reaction rate for HOCl + HCl in pure water is low (Donaldson et al.<sup>1</sup>). Experimental data noted above indicated that the reaction rate of HOCl + HCl increases with acidity of H<sub>2</sub>SO<sub>4</sub> solution. The data from the experimental studies noted above were fit to the model without bias. Using the same error analysis discussed in the note for N<sub>2</sub>O<sub>5</sub> uptake on sulfuric acid, a detailed kinetic model yields a 33.4% error (one sigma fit to the available data set, with  $\sigma_m = 33.3\%$  and  $\sigma_d = 3.0\%$ ).

In the cold stratosphere where T<190 K, the reaction of ClONO<sub>2</sub> + HCl is so fast that HCl is depleted which slows down the reaction of HOCl + HCl. As shown in Table A-4 in Shi et al., the effect of HCl depletion on the HOCl reactive uptake coefficient (due to reaction with ClONO<sub>2</sub> inside/on the surface of particles) is taken into account via the factor  $F_{HCl}$  (also see the note on chlorine nitrate/hydrochloric acid reactive uptake on sulfuric acid surfaces).

- 84. HOCl + HBr on H<sub>2</sub>O(s).** Chu and Chu<sup>1</sup> measured  $\gamma$  at 189 K to be in the range from 0.06 to 0.38 for HBr partial pressures ranging from  $1.1 \times 10^{-7}$  to  $6.6 \times 10^{-5}$  Torr. At 220 K they measured  $\gamma$  in the range from 0.01 to 0.07 for HBr partial pressures in the range from  $7.2 \times 10^{-7}$  to  $1.3 \times 10^{-5}$  Torr. These  $\gamma$  values were estimated assuming the area of the ice surface to be equal to the geometric area of the cylindrical flow reactor; corrections for surface porosity effects range from a factor of 3 to 10 lower.

- (1) Chu, L.; Chu, L. T. Heterogeneous reaction HOCl + HBr → BrCl + H<sub>2</sub>O on ice films. *J. Phys. Chem. A* **1999**, *103*, 691-699.
- 85. HOCl + HBr on H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Abbatt and Nowak<sup>1</sup> measured uptake of HOCl in the presence of excess HBr on a 69.3 wt% sulfuric acid solution in a wetted wall flow reactor at 228 K. A second order bulk reaction rate constant,  $k^{\text{II}}$ , of  $2 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$  was derived; this is a factor of ~10 faster than HOBr + HCl under the same conditions. Since HOCl and HBr have variable solubilities under stratospheric conditions, characterizing this reaction with a simple uptake coefficient is not appropriate. A full reaction/solubility/liquid phase diffusion model will require further data.

- 86. HOCl + NaBr and KBr.** Rossi<sup>2</sup> reported studies of the uptake of HOCl in a Knudsen cell using KBr powders and spray-deposited thin films. Values for the initial uptake coefficients covered a wide range, from  $5 \times 10^{-3}$  to 0.2, due to changes in the surface from adsorbed reaction products. The major product initially was Br<sub>2</sub>, and subsequently BrCl and HOBr, with much smaller amounts of BrOCl and Br<sub>2</sub>O. The mechanism was interpreted as the formation of small amounts of HBr on the surface from hydrolysis of KBr, followed by the reaction of HOCl with adsorbed HBr to form BrCl which then reacts with KBr to form Br<sub>2</sub>. On frozen solutions of NaBr, Huff and Abbatt<sup>1</sup> observe reactivity of HOCl with uptake coefficients between 0.02 and 0.04 at 233 K in a coated-wall flow tube. Br<sub>2</sub> is the gas-phase product, thought to arise from the intermediate BrCl reacting with the bromide film. Although the kinetics are faster on the most acidic films (pH 2), there is no dependence of the acidity of the solution from pH 4 to 10.

- 87. ClNO + H<sub>2</sub>O(l).** Scheer et al.<sup>1</sup> used droplet train and wetted wall flow reactor measurements to determine reactive uptake coefficients for ClNO over a temperature range of 273–293 K. Measured values show a weak negative temperature dependence ranging from 0.12 at 273 K to 0.0058 at 293 K. The reaction was shown to be base catalyzed producing HONO.

- 90. ClNO<sub>2</sub> + KBr, NaBr, NaI and NaCl.** Caloz et al.<sup>3</sup> measured the uptake of ClNO<sub>2</sub> on solid KBr at room temperature using a Knudsen cell and salt samples in the form of powders, spray-deposited films, polished windows and depolished windows. The uptake coefficient increased with the number of layers of salt powders; correction of the uptake coefficients using the pore diffusion model gave initial uptake coefficients of  $(1.0-1.3) \times 10^{-4}$ , in agreement with values measured for the spray-deposited film ( $1.0 \times 10^{-4}$ ) and depolished window ( $1.0 \times 10^{-4}$ ). The value for the polished window was an order of magnitude smaller, as expected since this has much less surface-adsorbed water (SAW) that assists in keeping the surface from becoming passivated. The yield of Br<sub>2</sub> relative to ClNO<sub>2</sub> lost was  $0.55 \pm 0.2$ . Using a diffusion tube method, Koch and Rossi<sup>7</sup> measured an uptake coefficient of  $2.0 \times 10^{-4}$ , in reasonable agreement with the Knudsen cell results.

The uptake of ClNO<sub>2</sub> on aqueous solutions of NaBr has been shown to increase with the concentration of NaBr. Frenzel et al.<sup>5</sup> measured the uptake of ClNO<sub>2</sub> on  $(0.5-5) \times 10^{-3}$  M NaBr solutions from 275–291 K using a wetted wall flow tube apparatus; the values of  $\gamma$  increased from  $1.2 \times 10^{-5}$  to  $4.0 \times 10^{-5}$  over this range of NaBr concentrations. Schweitzer et al.<sup>9</sup> used a droplet train apparatus from 275–288 K;  $\gamma$  increased from  $8.6 \times 10^{-6}$  to  $9.4 \times 10^{-4}$  as the NaBr concentration increased from  $10^{-4}$  to 1.0 M. The main product was Br<sub>2</sub>, with traces of BrNO<sub>2</sub> and BrCl. In a subsequent study,<sup>10</sup> they applied a wetted wall flow tube method from 275–293 K and reported uptake coefficients that were independent of temperature over this range, but again increased with the concentration of NaBr:  $\gamma$  increased from  $7.1 \times 10^{-6}$  at  $10^{-4}$  M NaBr to  $9.2 \times 10^{-4}$  at 1.0 M. Fickert et al.<sup>4</sup> used a wetted wall flow tube at 274 K and measured an uptake coefficient of  $1.1 \times 10^{-5}$  for  $10^{-4}$  M NaBr, increasing to  $1.1 \times 10^{-4}$  for  $10^{-2}$  M NaBr. The major gas phase products were Br<sub>2</sub> and BrNO<sub>2</sub>, with the yield of BrNO<sub>2</sub> decreasing as the initial bromide ion concentration in solution increased. The mass accommodation coefficient for ClNO<sub>2</sub> on aqueous solutions at 275 K was measured to be  $(9 \pm 4) \times 10^{-3}$ . A Knudsen cell study by Beichert and Finlayson-Pitts<sup>2</sup> found  $\gamma < 10^{-5}$  on NaCl powders at 298 K.

The uptake of ClNO<sub>2</sub> on solutions of NaI was studied by George et al.<sup>6</sup> and by Schweitzer et al.<sup>9,10</sup> The uptake coefficient increases with the concentration of NaI. For example, George et al.<sup>6</sup> reported that  $\gamma_0$  increased from  $1.1 \times 10^{-3}$  to  $6.6 \times 10^{-3}$  as the iodide concentration increased from  $10^{-3}$  M to  $10^{-2}$  M at 280 K. This is consistent with the results of Schweitzer et al.<sup>9,10</sup> who reported that  $\gamma_0$  increased from  $3.1 \times 10^{-5}$  to  $4.5 \times 10^{-3}$  as the iodide concentration increased from  $10^{-4}$  M to  $10^{-2}$  M at 275 K.

The uptake of ClNO<sub>2</sub> on solutions of NaCl is much slower than on NaBr or NaI solutions. Behnke et al.<sup>1</sup> reported uptake of ClNO<sub>2</sub> at 291 K using a wetted wall flow tube, with uptake coefficients decreasing as the NaCl concentration increased. At 0.1 M NaCl,  $\gamma_0 = (3.1 \pm 0.3) \times 10^{-6}$  but at 4.6 M NaCl, the value was about an order of magnitude smaller,  $\gamma_0 = (0.27 \pm 0.02) \times 10^{-6}$ . They proposed that this was due to the common ion effect owing to the reversible hydrolysis of ClNO<sub>2</sub> to Cl<sup>-</sup> + NO<sub>2</sub><sup>+</sup>.

Roberts et al.<sup>8</sup> report that ClNO<sub>2</sub> produces Cl<sub>2</sub> when exposed to solutions of chloride with concentrations as low as 0.05 M, when the pH is less than 2.

- 91. ClONO<sub>2</sub> + H<sub>2</sub>O(s).** Measurement of  $\gamma = 0.3 (+0.7, -0.1)$  (Hanson and Ravishankara<sup>5</sup>) significantly exceeds early measurements of Molina et al.,<sup>11</sup> Tolbert et al.,<sup>14</sup> Leu,<sup>9</sup> and Moore et al.<sup>12</sup> but agrees reasonably well with subsequent measurements by Chu et al.,<sup>2</sup> Zhang et al.,<sup>15</sup> and Fernandez et al.<sup>3</sup> when geometrical surface areas are assumed for analysis. Previous measurements were probably complicated by NAT formation on the surface (Hanson and Ravishankara<sup>6</sup> and Chu et al.<sup>2</sup>). Lower levels of ClONO<sub>2</sub>(g) used by Hanson and Ravishankara<sup>5</sup> minimized this surface saturation problem. Also, using lower ClONO<sub>2</sub> concentrations, Zhang et al. obtained a reaction probability of  $0.08 \pm 0.02$  at 195 K, Fernandez et al. measured 0.1, and values were 0.03 to 0.13 from Chu et al. Subsequent Knudsen cell measurements at 180 and 200 K by Oppliger et al.<sup>13</sup> showed initial uptake  $\gamma_s$  in the 0.2 to 0.4 range. Measured reaction products were HNO<sub>3</sub> and HOCl. All of the HNO<sub>3</sub> and much of the HOCl is retained on the surface under polar stratospheric conditions (Hanson and Ravishankara<sup>5,6</sup>). Hanson<sup>4</sup> deposited ClONO<sub>2</sub> on H<sub>2</sub><sup>18</sup>O enriched ice and detected H<sup>18</sup>OCl showing the Cl-ONO<sub>2</sub> bond is broken at 191 K.
- Data plots confirm a trend showing that at a high density of ClONO<sub>2</sub>, the product HNO<sub>3</sub> covers the ice surface preventing the further reaction of ClONO<sub>2</sub> with H<sub>2</sub>O molecules on the surface. Therefore, data obtained at high ClONO<sub>2</sub> densities ( $>10^{14}$  molecules/cm<sup>3</sup>) are excluded from further evaluation. An experiment (Berland et al.<sup>1</sup>) using a laser-induced thermal desorption technique yielded a much lower value of ClONO<sub>2</sub> reaction probability at 190 K (about 3 orders of magnitude lower) after extrapolating the results obtained at temperatures of 140 K and below. We also exclude this point in the averaging of data since the physical characteristics of ice surfaces at these very low temperatures may not be very representative of those found at stratospheric temperatures. Selected data show no temperature dependence between T = 180 and 200 K and averaged  $\gamma_0 = 0.28 \pm 0.25$ . Again, within the experimental accuracy, the Hanson and Ravishankara<sup>6,7</sup> and Chu et al.<sup>2</sup> data show that uptake measurements are nearly independent of ice substrate thickness. See Henson et al.<sup>8</sup> for discussion of a model which accounts for the effect of HNO<sub>3</sub> on the reaction ClONO<sub>2</sub> on water and nitric acid ice surfaces. The reactivity of ClONO<sub>2</sub> on ice, as modeled with high level ab initio methods and simulations with four water molecules is consistent with the above laboratory results, i.e., the uptake coefficient is modeled to be close to 0.1 at 180 K with a strong negative temperature dependence (Loerting et al.<sup>10</sup>).

Zondlo et al.<sup>16</sup> report the formation of a supercooled H<sub>2</sub>O/HNO<sub>3</sub> liquid layer at 185 K as a reaction product, forming NAT or NAD only after decreasing the relative humidity below the ice frost point. This effect is similar to that resulting from the interaction of gaseous HNO<sub>3</sub> or N<sub>2</sub>O<sub>5</sub> with the ice surface. These authors measured  $\gamma = (3 \pm 2) \times 10^{-3}$  at 185 K for the reaction of ClONO<sub>2</sub> with this supercooled liquid layer.

- 93. ClONO<sub>2</sub> + HNO<sub>3</sub>•nH<sub>2</sub>O(s).** Hanson and Ravishankara<sup>3</sup> report a  $\gamma$  value of 0.006 at 201 K for the ClONO<sub>2</sub> reaction with the water on NAT (HNO<sub>3</sub>•nH<sub>2</sub>O). However, these authors present re-analyzed and additional data with  $\gamma \approx 0.001$  at 191 K in Hanson and Ravishankara.<sup>4,5</sup> Similar experiments (Moore et al.<sup>8</sup> and Leu et al.<sup>7</sup>) report a larger value of  $0.02 \pm 0.01$  which falls very rapidly as slight excesses of H<sub>2</sub>O above the 3/1 H<sub>2</sub>O/HNO<sub>3</sub> ratio for NAT are removed. In general, it is difficult to know that only NAT is formed when freezing from solution; it is likely that the high value reflects the reactivity on water ice that will form when the solution stoichiometry is water rich. They measured  $\gamma$  of less than  $1 \times 10^{-6}$  for slightly water-poor NAT surfaces. Abbott and Molina<sup>1</sup> report  $\gamma$  values reaching 0.002 at 202 K and high RH. Hanson and Ravishankara<sup>4</sup> reported that  $\gamma$  for this reaction increases by a factor of 4 as the surface temperature increases from 191 to 211 K. However, Knudsen cell measurements at 185 K by Barone et al.<sup>2</sup> reported  $\gamma = 0.004$  at a relative humidity (RH) of 100%, rising to 0.007 near RH = 120%, indicating a possible mild negative temperature dependence when high RH values from this and other studies are compared. Excluding the JPL data,<sup>7,8</sup> the other data obtained at high RH (~90%) were averaged, assuming no temperature dependence, to yield  $\gamma = 0.0043 \pm 0.0021$ . The strong dependence on RH and the possible temperature dependence suggest that systematic error probably exceeds the calculated statistical error. Within the experimental accuracy, the data of Hanson and Ravishankara<sup>4,5</sup> show that measured uptake coefficients are independent of ice substrate thickness. Barone et al. report very similar uptake coefficients

for nitric acid dihydrate (NAD) as for NAT as a function of RH at 202 K. See Henson et al.<sup>6</sup> for discussion of a model which accounts for the effect of HNO<sub>3</sub> on the reaction of ClONO<sub>2</sub> on water and nitric acid ice surfaces.

94. **ClONO<sub>2</sub> + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Results from wetted-wall flow tube (Hanson and Ravishankara<sup>5</sup>) Knudsen cell reactor (Manion et al.<sup>6</sup>), aerosol flow tube (Hanson and Lovejoy<sup>3</sup>), and droplet train uptake (Robinson et al.<sup>7</sup>) experiments supplement older wetted-wall flow tube (Hanson and Ravishankara<sup>4</sup>) and Knudsen cell measurements (Rossi et al.<sup>8</sup> and Tolbert et al.<sup>10</sup>). Although earlier Knudsen cell measurements probably suffered from surface saturation, more recent results compare well with those from other techniques. Saturation free results, available over a temperature range of 200–265 K and a H<sub>2</sub>SO<sub>4</sub> concentration range of 39 to 75 wt%, were fit to a phenomenological model developed by Robinson et al.<sup>7</sup> Measured  $\gamma$  values depend strongly on H<sub>2</sub>SO<sub>4</sub> concentration and vary modestly with temperature, with a trend to somewhat higher values for the 210–220 K temperature range. The temperature-dependent uptake model takes into account the temperature and composition dependence of the effective Henry's Law constant, liquid phase diffusion coefficient, and the liquid phase hydrolysis rate constant. The hydrolysis reaction was treated by modeling two reaction channels, a direct hydrolysis process dominating reaction at low H<sub>2</sub>SO<sub>4</sub> concentrations with a reaction rate proportional to water activity and a proton-catalyzed reaction with a rate proportional to H<sup>+</sup> activity, which dominates at higher acid concentrations.
- The data fit to the original Robinson et al. model have been supplemented by additional wetted-wall flow tube and aerosol flow tube data from Hanson<sup>2</sup> and aerosol flow tube data from Ball et al.<sup>1</sup> A revised kinetic model (Shi et al.<sup>9</sup>) incorporating these data has been developed that is based on the earlier work of Robinson et al.<sup>7</sup> In this model,  $\gamma$  is calculated using the expression

$$\frac{1}{\gamma} = \frac{1}{\alpha} + \frac{1}{\Gamma_b^{H_2O}}$$

where,

$$\Gamma_b^{H_2O} = \frac{4H_{ClONO_2}RT}{\bar{c}} \left( D_{ClONO_2} k_{hydr} \right)^{1/2}$$

The detailed parameterizations for H<sub>ClONO<sub>2</sub></sub>, D<sub>ClONO<sub>2</sub></sub>, and k<sub>hydr</sub> are given in the Appendix in Shi et al.<sup>9</sup> As was the case for N<sub>2</sub>O<sub>5</sub> hydrolysis k<sub>hydr</sub> is seen to have a direct and an acid catalyzed channel. Using the same error analysis approach as in the note on N<sub>2</sub>O<sub>5</sub> uptake, the model error is about 32.4% (1 $\sigma$ ), with  $\sigma_m = 32.2\%$  and  $\sigma_d = 4.0\%$ .

In the calculation of the chlorine activation ( $\text{Cl}_2$  production) rate under stratospheric conditions, one needs to take into account the competition between the reactions of  $\text{ClONO}_2 + \text{H}_2\text{O}$  and  $\text{ClONO}_2 + \text{HCl}$ . The presence of HCl will depress the reaction probability of  $\text{ClONO}_2$  with  $\text{H}_2\text{O}$ .

- 95.  $\text{ClONO}_2 + \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}(\text{s})$  and  $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}(\text{s})$ .** Measurements by Hanson and Ravishankara<sup>1</sup> and Zhang et al.<sup>2</sup> demonstrate that the reaction probability on the tetrahydrate is a strong function of both temperature and relative humidity, both of which affect the level of adsorbed  $\text{H}_2\text{O}$ . Both groups covered the temperature range of 192–205 K. The reaction is slowest at higher temperatures and lower relative humidities. Zhang et al.<sup>2</sup> have parameterized their data in the form of  $\log \gamma = a_1 + a_2 \log x + a_3 \log^2 x$ ; for 195 K and  $x = \text{water partial pressure in Torr}$ :  $a_1 = 10.12$ ,  $a_2 = 5.75$  and  $a_3 = 0.62$ ; for a water partial pressure of  $3.4 \times 10^{-4}$  Torr and  $x = T(\text{K})$  between 182 and 206:  $a_1 = 318.67$ ,  $a_2 = -3.13$  and  $a_3 = 0.0076$ . Zhang et al.<sup>3</sup> have also measured a low value of  $\gamma \sim 2 \times 10^{-4}$  on sulfuric acid monohydrate at 195 K.

  - (3) Zhang, R.; Leu, M.-T.; Keyser, L. F. Sulfuric acid monohydrate: Formation and heterogeneous chemistry in the stratosphere. *J. Geophys. Res.* **1995**, *100*, 18,845-18,854.
- 96.  $\text{ClONO}_2 + \text{HCl} + \text{H}_2\text{O}(\text{s})$ .** Reaction probabilities of 0.27 (+0.73, -0.13) (Leu<sup>6</sup>) and 0.05 to 0.1 (Molina et al.<sup>8</sup>) were reported at 195 and 185 K, respectively. Abbatt and Molina<sup>1</sup> and Hanson and Ravishankara<sup>4</sup> report that a portion of the reaction may be due to  $\text{HOCl} + \text{HCl} \rightarrow \text{Cl}_2 + \text{H}_2\text{O}$ , with HOCl formed from  $\text{ClONO}_2 + \text{H}_2\text{O}(\text{s}) \rightarrow \text{HOCl} + \text{HNO}_3(\text{s})$ . Hanson and Ravishankara<sup>5</sup> saw no enhancement of the  $\text{ClONO}_2$  reaction probability when  $\text{H}_2\text{O}(\text{s})$  is doped with HCl. Their preferred value at 192 K is  $\gamma = 0.3$ , but this is consistent with  $\gamma = 1$ . Chu et al.<sup>2</sup> also report a value of 0.27 ( $\pm 0.19$ ) at 188 K, assuming no correction for porosity, but suggest the true value is 0.10 ( $\pm 0.08$ ). Using a Knudsen cell technique and looking at initial uptake, Oppenheimer et al.<sup>9</sup> measured  $\gamma = 0.7$  at 180 K and 0.2 at 200 K with HCl in excess, and both Fernandez et al.<sup>3</sup> and McNeil et al.<sup>7</sup> report a value of >0.1 at close to 200 K. McNeil et al. report that this value is

substantially smaller at 218 K. Eliminating the Molina et al. points, which were taken at much higher ClONO<sub>2</sub> concentrations than the others, plots of the remaining data show no obvious bias when plotted as a function of reactant concentration or temperature (180–200 K). Their average value  $\gamma = 0.26 \pm 0.06$ . The Oppliger et al. data were presented for two HCl concentrations, differing by a factor of three. All points from both HCl concentrations were included since all the data were generally consistent with previous measurements, although the higher HCl concentrations did tend to produce modestly higher uptake coefficients. Until a fuller model is available, a single temperature independent value with a moderate uncertainty due to surface porosity seems appropriate.

97. **ClONO<sub>2</sub> + HCl + HNO<sub>3</sub>•3H<sub>2</sub>O.** Measurements by Hanson and Ravishankara,<sup>3,4</sup> Leu and co-workers in Moore et al.<sup>6</sup> and Leu et al.,<sup>5</sup> and Abbott and Molina<sup>1</sup> all report high  $\gamma$  values ( $>0.1$ ) on NAT for temperatures between 192 and 202 K on water-rich NAT. Hanson and Ravishankara indicate that reaction probabilities on NAD are similar to those on NAT. The most recent NAT studies (Abbatt and Molina<sup>1</sup>) show a strong fall-off with relative humidity from  $\gamma > 0.2$  at 90% RH to 0.002 at 20% RH, indicating the necessity of sufficient water to solvate reactants. Within the limited measurements, data plots show no indication that the reaction probability of ClONO<sub>2</sub> + HCl depends on HCl and ClONO<sub>2</sub> gas phase concentrations or temperature between 191 and 202 K for water-rich NAT, but for nitric acid-rich NAT, there is a strong dependence on the partial pressure of HCl indicating that HCl is a limiting reagent on the surface under those conditions (Abbatt and Molina<sup>1</sup>). Averaged data yield  $\gamma = 0.23 \pm 0.10$  for the water-rich case. Carslaw and Peter<sup>2</sup> have published a model of this reaction and its dependence on HCl uptake.

- 98. ClONO<sub>2</sub> + HCl + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Early work by Tolbert et al.<sup>10</sup> and Hanson and Ravishankara<sup>4</sup> indicated that the presence of HCl had little effect on the reaction of ClONO<sub>2</sub> with concentrated sulfuric acid (>65 wt% H<sub>2</sub>SO<sub>4</sub>). Subsequent realization that HCl would be more soluble, and therefore a more potent reactant, in the colder, more dilute sulfuric acid aerosols characteristic of the polar stratosphere led to additional investigations by Hanson and Ravishankara,<sup>5</sup> Zhang et al.,<sup>11</sup> Elrod et al.,<sup>1</sup> and Hanson.<sup>2</sup> All these measurements show a strong dependence of reactivity on HCl solubility, which in turn depends on water activity. The solubility of HCl in a wide range of sulfuric acid solutions has been experimentally determined by a range of techniques that agree well with current thermodynamic models. See Robinson et al.<sup>8</sup> for a review. Hanson and Lovejoy<sup>3</sup> measured a reacto-diffusive length, l, of only  $0.009 \pm 0.005 \mu\text{m}$  for 60 wt% H<sub>2</sub>SO<sub>4</sub> in an aerosol flow reactor. (See Hanson et al.<sup>6</sup> for a definition of l) This is a factor of four lower than the value for the hydrolysis reaction of ClONO<sub>2</sub> showing the significant enhancement of ClONO<sub>2</sub> uptake due to HCl.

The ClONO<sub>2</sub> + HCl reaction on/in sulfuric acid has been modeled in Shi et al.<sup>9</sup> using the same phenomenological model for ClONO<sub>2</sub> hydrolysis driven uptake by sulfuric acid. Since the effect of HCl on the ClONO<sub>2</sub> uptake is to increase the ClONO<sub>2</sub> pseudo-first-order reaction rate, the model of ClONO<sub>2</sub> uptake (see note on ClONO<sub>2</sub> uptake on sulfuric acid) should include the pseudo first order reaction rate,  $k_{\text{HCl}}$ . The formulation of  $k_{\text{HCl}}$  is found in the appendix in Shi et al.<sup>9</sup> It is likely that the ClONO<sub>2</sub> reaction with HCl, like the ClONO<sub>2</sub> hydrolysis reaction, is acid catalyzed via protonated HClONO<sub>2</sub><sup>+</sup>, where Cl<sup>+</sup> is activated as in the case of HOCl + HCl. For the ClONO<sub>2</sub> + HCl reaction, there is also a surface reaction (Hanson<sup>2</sup>). Hanson proposed that  $\Gamma_s$ , the effective uptake rate due to surface reactions, is linearly proportional to water activity; however, the calculated value of  $\gamma_o$  at 250 K and 60 wt% H<sub>2</sub>SO<sub>4</sub> using his formulation is 0.02 (here  $\gamma_o \sim \Gamma_s$ ), which is contradictory to his aerosol flow reactor result, which yielded  $\gamma_o = 0.0079$  (here  $\gamma_o \sim \Gamma_b$ ) (Hanson and Lovejoy<sup>3</sup>). In the model presented in the Shi et al. appendix, it is assumed that that  $\Gamma_s$  is linearly proportional to Henry's law constant of ClONO<sub>2</sub>, rather than the water activity. The temperature dependence of  $\Gamma_s$  is determined, based on two measured values of  $\Gamma_s$  at 203 K (Hanson<sup>2</sup>) and 250 K (Hanson and Lovejoy<sup>3</sup>). The model yields a value of  $\gamma_o \sim 0.011$  (here  $\gamma_o \sim \Gamma_s$ ), which is close to the measured value.

In the stratosphere, when the reaction rate of ClONO<sub>2</sub> with HCl exceeds the flux of HCl to the particle surface, HCl is depleted. This, in turn, will depress the rate of both the ClONO<sub>2</sub> and HOCl + HCl reactions, and increase the ClONO<sub>2</sub> hydrolysis rate. Shi et al.<sup>9</sup> have proposed a model in which this effect is taken into account by including a factor  $F_{\text{HCl}}$  (see Table A-3 in Shi et al.). The formulation of  $F_{\text{HCl}}$  is based on scaling HCl reaction and accommodation fluxes. This flux correction is not exact (i.e., it does not rigorously calculate the HCl surface or bulk concentration) but provides a good approximation to the expected reduction in HCl + ClONO<sub>2</sub>/HOCl reactivity and, just as importantly, the effective increase in ClONO<sub>2</sub> + H<sub>2</sub>O reactivity when  $p_{\text{ClONO}_2} > p_{\text{HCl}}$ . This is particularly relevant during cold Cl activation events when HCl can be removed almost completely (i.e., see Jaegle et al.<sup>7</sup>).

Using the same error analysis approach as in the note on N<sub>2</sub>O<sub>5</sub> uptake by sulfuric acid, the error of using the model in the Appendix is about 40.0% (one sigma), with  $\sigma_m = 39.8\%$  and  $\sigma_d = 4.0\%$ .

- 99. ClONO<sub>2</sub>+HCl + H<sub>2</sub>SO<sub>4</sub>•H<sub>2</sub>O(s) and H<sub>2</sub>SO<sub>4</sub>•4H<sub>2</sub>O(s).** This reaction has been studied by Hanson and Ravishankara<sup>1</sup> and Zhang et al.<sup>2</sup> The reaction probability is strongly dependent on the thermodynamic state of the SAT surface, which is controlled by the temperature and the water vapor partial pressure. At a water vapor pressure of  $5.6 \times 10^{-4}$  Torr the measured  $\gamma$  drops by over two orders of magnitude as the SAT surface temperature rises from 195 to 206 K. The results from the two groups are in qualitative agreement, but sample different H<sub>2</sub>O and HCl partial pressures. Zhang et al. have parameterized their data as a function of water partial pressure (at 195 K) and temperature (both at an HCl partial pressure of 4 to  $8 \times 10^{-7}$  Torr) in the form  $\log \gamma = a_1 + a_2 \log x + a_3 (\log x)^2$ . For H<sub>2</sub>O partial pressure,  $a_1 = 5.25$ ,  $a_2 = 1.91$ , and  $a_3 = 0.0$ ; for T(K),  $a_1 = 175.74$ ,  $a_2 = -1.59$ , and  $a_3 = 0.0035$ . Care must be taken in extrapolating either data set to lower HCl concentrations. Zhang et al.<sup>3</sup> measured no enhancement of ClONO<sub>2</sub> uptake on sulfuric acid monohydrate at 195 K with  $(2-8) \times 10^{-7}$  Torr of HCl present, implying  $\gamma < 1 \times 10^{-4}$ .

- 101. ClONO<sub>2</sub> + NaCl.** Timonen et al.<sup>10</sup> studied the uptake of ClONO<sub>2</sub> on NaCl powders at 296 K and 225 K using a flow tube. Complete deactivation of the surface was observed at 225 K but not at 296 K. The uptake coefficients, after correction (typically by an order of magnitude) using the pore diffusion model of Keyser et al.<sup>7,8</sup> were  $\gamma_0 = (4.6 \pm 3.1) \times 10^{-3}$  ( $1\sigma$ ) at 296 K and  $\gamma_0 = (6.7 \pm 3.2) \times 10^{-3}$  ( $1\sigma$ ) at 225 K. Similarly low values for the uptake coefficient are reported by Zelenov et al.<sup>11</sup> using a flow tube approach. On the other hand, Caloz et al.<sup>2</sup> used a Knudsen cell and found that the initial uptake coefficient was  $0.23 \pm 0.06$ , independent of the type of salt used (powders, single crystals, deposited salt films) and without applying a correction for pore diffusion since no mass dependence for  $\gamma$  was observed; in similar studies. Aguzzi and Rossi<sup>1</sup> measured a value of  $\gamma_0 = 0.10 \pm 0.05$  for the uptake of ClONO<sub>2</sub> on NaCl and  $0.27 \pm 0.10$  for uptake on the unreactive NaNO<sub>3</sub> and Na<sub>2</sub>SO<sub>4</sub> salts. The Cl<sub>2</sub> yield was 100% for NaCl, in agreement with the earlier studies<sup>2,10</sup> but  $27 \pm 7\%$  on the unreactive salts. Koch and Rossi<sup>9</sup> used a diffusion tube technique to measure a value of 0.1 for the uptake coefficient. Gebel and Finlayson-Pitts<sup>5</sup>

used a Knudsen cell and measured an initial value of  $\gamma_0 = 0.14 \pm 0.11$  ( $2\sigma$ ) and a steady-state value of  $\gamma = (3.9 \pm 1.8) \times 10^{-2}$ , but concluded that approximately two layers of salt were sampled in these multi-layer experiments. The use of a single or sub-single layer of NaCl gave a steady state value corrected using the model of Hoffman et al. of  $\gamma = (2.4 \pm 1.2) \times 10^{-2}$ .<sup>6</sup> The source of the very disparate results from the different groups and techniques is not clear. All studies agree that the yield of Cl<sub>2</sub> is 100%, consistent with ClONO<sub>2</sub> + NaCl → Cl<sub>2</sub> + NaNO<sub>3</sub> as observed earlier,<sup>4</sup> with small amounts of HOCl from hydrolysis of ClONO<sub>2</sub> on the surface being observed in the presence of water.

Deiber et al.<sup>3</sup> studied the uptake of ClONO<sub>2</sub> on water, NaCl and NaBr solutions using a droplet train flow reactor. The uptake coefficient was the same on water and 0.1 M NaCl, and Cl<sub>2</sub> was observed as the gas phase product.

- 102. ClONO<sub>2</sub> + KBr and NaBr.** Caloz et al.<sup>2</sup> and Aguzzi and Rossi<sup>1</sup> report a rapid uptake of ClONO<sub>2</sub> on KBr solid salts at room temperature,  $\gamma_0 = 0.35 \pm 0.06$  and  $\gamma_0 = 0.18 \pm 0.07$  respectively; corrections for pore diffusion were not applied but are not expected to be large at these high uptake coefficients (see Introduction). This is consistent with a value of 0.1 measured by Koch and Rossi<sup>4</sup> using a diffusion tube technique. The reaction products are BrCl, Br<sub>2</sub> and Cl<sub>2</sub>. BrCl is the initial reaction product formed from ClONO<sub>2</sub> + KBr → BrCl + KNO<sub>3</sub>. Br<sub>2</sub> is generated in a secondary reaction of BrCl with KBr: BrCl + KBr → Br<sub>2</sub> + KCl. Cl<sub>2</sub> is then formed as the surface KBr is converted to KCl, which then reacts with ClONO<sub>2</sub>. Deiber et al.<sup>3</sup> studied the uptake of ClONO<sub>2</sub> on water, NaCl and NaBr solutions using a droplet train flow reactor. On NaBr, the uptake increased from 0.041 at 0.01 M NaBr to 0.073 at 1 M NaBr. From the dependence on the NaBr concentration, a value for the mass accommodation coefficient for ClONO<sub>2</sub> of  $0.108 \pm 0.033$  ( $2\sigma$ ) was obtained. The gas phase products were BrCl and Br<sub>2</sub>, the latter formed by secondary reactions of BrCl with Br<sup>-</sup>.

**103. ClONO<sub>2</sub> + sea salt.** Gebel and Finlayson-Pitts<sup>1</sup> reported a rapid reaction between ClONO<sub>2</sub> and synthetic sea salt, with initial values based on the geometric sample area of  $\gamma_0 = 0.42$  and steady-state values of  $\gamma = 0.16$  ( $2\sigma$ ). These were measured with multiple salt layers (3–236) but corrections for diffusion into underlying layers for such high uptake coefficients are relatively small, less than a factor of three. The yield of Cl<sub>2</sub> was  $78 \pm 13\%$ ; small amounts of HCl and HOCl were also observed as products. The recommended lower limit is based on these studies and the rapid uptake of other reactive species such as HNO<sub>3</sub> and N<sub>2</sub>O<sub>5</sub>.

**104. ClONO<sub>2</sub> + HBr + H<sub>2</sub>O(s) and HNO<sub>3</sub>•nH<sub>2</sub>O(s).** This reaction was studied by Hanson and Ravishankara<sup>2</sup> on water ice and NAT near 200 K. A diffusion-limited reaction probability of >0.3 was observed. Allanic et al.<sup>1</sup> measured  $\gamma = 0.56 \pm 0.11$  at 200 K on water ice, observing Cl<sub>2</sub> and Br<sub>2</sub> to be formed in yields of 100% and 66 to 80%, respectively, in the range 180 to 200 K.

**106. CF<sub>x</sub>Cl<sub>(4-x)</sub> (x=0–3) and CF<sub>2</sub>Br<sub>2</sub> + Al<sub>2</sub>O<sub>3</sub>(s).** Robinson et al.<sup>3</sup> reported steady-state dissociative uptake of CF<sub>2</sub>Cl<sub>2</sub> and CF<sub>2</sub>Br<sub>2</sub> on  $\alpha$ -alumina surfaces at 210 and 315 K. Reaction probabilities of about  $1 \times 10^{-3}$  at 210 K were measured by monitoring the amounts of surface species bonded to the Al<sub>2</sub>O<sub>3</sub> substrate. A re-analysis (Robinson et al.<sup>4</sup>) lowered this value by about a factor of 50. Moderate surface dosage with water vapor did not quench the reaction. In addition, Dai et al.<sup>1</sup> and Robinson et al.<sup>2</sup> studied dissociative chemisorption of CF<sub>3</sub>Cl, CF<sub>2</sub>Cl<sub>2</sub>, CFCI<sub>3</sub>, and CCl<sub>4</sub> on dehydroxylated  $\gamma$ -alumina powders. The obtained reactive uptake probabilities ranging from  $0.4 \times 10^{-5}$  for CFCI<sub>3</sub> to  $1.0 \times 10^{-5}$  for CFCI<sub>3</sub> over a temperature range of 120 to 300 K. HCl and halomethyl radicals were observed as desorption products. Loss of these products may point to somewhat higher  $\gamma$ s, since they were measured by integrating halogen bound to Al<sub>2</sub>O<sub>3</sub> substrates.

**107. BrCl + NaCl, NaBr, KBr and NaI.** The uptake of BrCl on solid NaCl and KBr using a Knudsen cell has been reported by Aquuzzi and Rossi,<sup>1</sup> yielding 298 K values of  $6 \times 10^{-2}$  for NaCl and 0.14 on KBr. An earlier preliminary study from the same group reported a value at  $\gamma > 0.1$  on KBr.<sup>2</sup> Insufficient data are available to make a recommendation.

Katrib et al.<sup>4</sup> measured the uptake of BrCl on aqueous solutions of NaI over the temperature range from 273 to 288 K; the uptake coefficient increased from  $0.37 \times 10^{-2}$  to 0.7 as the I<sup>-</sup> concentration increased from  $1 \times 10^{-4}$  to 0.5 M NaI. The complex dependence on the I<sup>-</sup> concentration indicated that a surface reaction was occurring at the air-solution interface.

Huff and Abbatt<sup>3</sup> studied the loss of BrCl on frozen bromide salt solutions at 233 K, finding that the uptake coefficients vary between 0.02 and 0.04 depending on the bromide concentration, independent of solution acidity.

**108. Br<sub>2</sub> + NaCl, KBr and NaI.** Only one report of the uptake of Br<sub>2</sub> on solid NaCl and KBr using a Knudsen cell is available<sup>1</sup> as part of a study of BrONO<sub>2</sub> uptake on salts. The uptake coefficient for Br<sub>2</sub> was  $4 \times 10^{-3}$  on NaCl and  $3 \times 10^{-3}$  on KBr. Insufficient data are available to make a recommendation.

Hu et al.<sup>2</sup> measured the uptake of Br<sub>2</sub> on aqueous solutions of NaI using a droplet train flow reactor over the temperature range of 263 to 293 K. The measured uptake coefficients decreased from 0.33 at 263 K to 0.08 at 293 K, with evidence for a significant contribution from a reaction at the interface between Br<sub>2</sub> and I<sup>-</sup>.

**109. BrO + H<sub>2</sub>O(s), H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l) and NaCl(aq).** Abbatt<sup>1</sup> used a coated flow tube technique to measure heterogeneous uptake on water ice, 60 and 70 wt% H<sub>2</sub>SO<sub>4</sub> at 213 K, and 23 wt% aqueous NaCl at 253 K. He obtained  $\gamma(\text{ice}) = (1.0 \pm 0.4) \times 10^{-3}$ ,  $\gamma(60 \text{ wt\% H}_2\text{SO}_4) = (7 \pm 2) \times 10^{-4}$ ,  $\gamma(70 \text{ wt\% H}_2\text{SO}_4) = (5 \pm 2) \times 10^{-4}$  and  $\gamma(23 \text{ wt\% NaCl}) < 3 \times 10^{-3}$ . He observed product Br<sub>2</sub>, indicating BrO self-reaction on both water ice and sulfuric acid solutions. Since reaction rate will depend on BrO concentrations, no recommendation is made for an atmospheric rate.

**110. HOBr + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** Hanson<sup>1</sup> reported that uptake of HOBr on 80 wt.% H<sub>2</sub>SO<sub>4</sub>, producing Br<sub>2</sub>. Br<sub>2</sub> and Br<sub>2</sub>O production was also observed by Iraci et al.<sup>2</sup> during Knudsen cell studies of HOBr uptake on 70 wt% uptake for temperatures below 228 K. These products probably arise from HOBr self-reaction, although impurities in the acid solution might also play a role. Iraci et al. discuss methods to correct HOBr uptake

data for the effects of self-reaction and secondary reactions with its products. The bulk phase self-reaction of HOBr noted above is not likely to be significant over the expected range of atmospheric concentrations.

- 112. HOBr + HCl + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O.** For the sulfuric acid reaction, Abbatt<sup>1</sup> measured  $\gamma$ s of ~ 0.1 to 0.2 for [HCl] > 1 × 10<sup>12</sup> cm<sup>-3</sup> over 68.8 wt% H<sub>2</sub>SO<sub>4</sub> at 228 K; yielding an estimated  $k^{\text{II}}_{\text{HCl+HOBr}} = 1.4 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$  with a factor of 2 uncertainty. Hanson and Ravishankara<sup>3</sup> also measured  $\gamma \leq 0.2$  (+0.2, -0.1) for 60 wt% H<sub>2</sub>SO<sub>4</sub> at 210 K. However, both of these measurements were based on significant underestimation of the solubility of HOBr in the relevant sulfuric acid solutions. More recent measurements by Waschewsky and Abbatt<sup>5</sup> indicate that the Henry's law constant for HOBr varies slightly with acidity between 60 to 70 wt% H<sub>2</sub>SO<sub>4</sub> and more strongly with temperature between 208 and 238 K. (For 59.7 wt% H<sub>2</sub>SO<sub>4</sub>, H (M atm<sup>-1</sup>) = 1.2 × 10<sup>6</sup> at 208 K and 2.2 × 10<sup>5</sup> at 228 K.) The HOBr + HCl second order liquid phase rate constant,  $k^{\text{II}}_{\text{HCl+HOBr}}$ , varies between 2 × 10<sup>5</sup> and 3 × 10<sup>8</sup> (M<sup>-1</sup> s<sup>-1</sup>) between 213 and 238 K over the same composition range (60–70 wt% H<sub>2</sub>SO<sub>4</sub>). Such a strong dependence on acid composition for the reaction rate of HOBr + HCl and the very small acid composition dependence for HOBr solubility in H<sub>2</sub>SO<sub>4</sub> solution might be partially due to the formation of H<sub>2</sub>OBr<sup>+</sup> in the acidic solution as discussed in their paper. However, this acid catalyzed reaction, i.e. H<sub>2</sub>OBr<sup>+</sup> + HCl, alone does not completely account for measured reaction rates over the acid composition range studied.

Using the Henry's Law data for HOBr reported by Waschewsky and Abbatt,<sup>5</sup> the limiting reagent will vary depending on atmospheric temperature (H<sub>2</sub>SO<sub>4</sub> wt%) and the concentrations of HOBr and HCl. For stratospheric conditions where [HOBr] is 10 pptv and [HCl] 1 ppbv, they predict dissolved HOBr will be in excess above 204 K and HCl in excess below 204 K for a H<sub>2</sub>O vapor partial pressure of 3 × 10<sup>-7</sup> atm. From their coated wall flow reactor uptake measurements, Waschewsky and Abbatt<sup>5</sup> derived expressions for  $k^{\text{II}}_{\text{HCl+HOBr}}$  and predicted uptake coefficients. For temperature between 204 and 218 K where HOBr is likely to be in excess, they calculated HCl uptake coefficients,  $\gamma_{\text{HCl}}$ , which range between 7 × 10<sup>-5</sup> and 9 × 10<sup>-5</sup>. For temperatures in the 202–198 K range, where dissolved HCl is likely to be excess, the calculated uptake coefficients for HOBr,  $\gamma_{\text{HOBr}}$ , of ~1 × 10<sup>-2</sup>. Hanson has reported Henry's law solubility data for 58–70 wt.% sulfuric acid and reactive uptake coefficients for HCl on HOBr doped sulfuric acid surfaces using a wetted wall flow reactor.<sup>2</sup> Hanson's reported that  $H_{\text{HOBr}}$  was independent of acid concentration at 250 K, however, the heat of solvation for HOBr derived is significantly lower (-12.5 ± 3.7 versus -9 ± 1 kcal/mol reported at lower temperatures by Waschewsky and Abbatt) that the values of H\* based on Hanson's data, taken from 250 to 270 K, are much higher than the prior study's when extrapolated to their lower

temperatures. Hanson's reported  $\gamma_{\text{HCl}}$  are strongly dependent on HOBr partial pressure and drop almost three orders of magnitude as the sulfuric acid concentration is raised from 58 to 95 wt%, possibly because HCl may be reacting with sulfuric acid at higher acid concentrations. The higher temperature  $k^{\text{II}}_{\text{HCl+HOBr}}$  values computed by Hanson for his data disagree, when extrapolated to lower temperatures with the values reported by Waschewsky and Abbatt as well as a prior lower temperature value reported by Hanson and Ravishankara.<sup>3</sup> Better agreement can be obtained if the solvation enthalpy reported by Hanson is used to adjust the  $H_{\text{HOBr}}$  values used in the earlier, lower temperature studies. Clearly, the HOBr + HCl reaction will be difficult to parameterize in a simple manner. Potential inconsistencies in their  $k^{\text{II}}_{\text{HCl+HOBr}}$  values, as discussed by Waschewsky and Abbatt<sup>5</sup> and Hanson<sup>2</sup> indicate that further measurements are required before this reaction can be definitively modeled. Iraci et al.<sup>4</sup> subsequently measured HOBr uptake over both of the temperature ranges covered in the prior experiments. Their derived  $H^*$  values agreed well with data from Waschewsky and Abbatt<sup>5</sup> at lower temperatures but fell far below Hanson's higher temperature measurements. Thus, it appears that HOBr + HCl kinetic parameters developed from analyses based on the Hanson<sup>2</sup> data may need to be reanalyzed.

- 114. HOBr + NaCl.** Studies have been done on solid salts and aqueous surfaces. On solids, Mochida et al.<sup>4</sup> studied the uptake of HOBr on NaCl using multi-layer powders (10–500  $\mu\text{m}$ ) in a Knudsen cell at room temperature. After correction (by about an order of magnitude) for diffusion into the underlying layers, they obtained values for the initial uptake coefficient in the range of  $(0.97\text{--}6.5) \times 10^{-3}$ , with the corrected values decreasing with increasing concentrations of HOBr. They attributed this to competition between the reaction of HOBr with NaCl and a self-reaction of HOBr on the surface:  $2 \text{ HOBr} \rightarrow \text{Br}_2 + \text{H}_2\text{O} + \frac{1}{2} \text{ O}_2$ . Their final value of  $\leq 6.5 \times 10^{-3}$  is based on their extrapolation back to very low HOBr concentrations. Both Br<sub>2</sub> and BrCl were observed as products. Chu et al.<sup>2</sup> measured the uptake of HOBr on NaCl at 250 K over a range of RH from 1.5 to 22.5%. After correcting the measured loss of HOBr by a factor of ~30 for diffusion into the underlying salt layers using the pore diffusion model, they obtained a value  $\gamma_0 = 5 \times 10^{-5}$ . The smaller value compared to the Knudsen cell results of Mochida et al.<sup>4</sup> may be due to the much lower temperature they used; BrCl was the only gas phase product observed. Huff and Abbatt<sup>3</sup> report reactivity with frozen NaCl solutions in a coated-wall flow tube at 233 K. Uptake coefficients were dependent on the

chloride concentration of the solution and on the acidity, with faster kinetics on the more acidic surfaces. BrCl was the only product observed.

Abbatt and Waschewsky<sup>1</sup> measured the uptake of HOBr on deliquesced 1–5 µm NaCl particles (75% RH); for particles at pH values of 0.3 and 7.2, a lower limit to the uptake coefficient of  $\gamma_0 > 0.2$  was measured. On unbuffered particles, the upper limit for the uptake coefficient was  $\gamma_0 < 1.5 \times 10^{-3}$  due to the limited availability of H<sup>+</sup> for the reaction between HOBr and Cl<sup>-</sup> to form BrCl. Somewhat smaller values have been measured by Pratte and Rossi<sup>5</sup> in another aerosol flow tube experiment, using acidified NaCl particles. Acidification was necessary for the reaction to be observable. In general, the uptake coefficients varied from 1 to  $10 \times 10^{-3}$  from 70 to 90% relative humidity. The particles were acidified with quite large amounts of H<sub>2</sub>SO<sub>4</sub>, and the authors show that the reactivity on pure H<sub>2</sub>SO<sub>4</sub> is less than that on the acidified salts. This could be a reason for the disagreement between the lower limit of Abbatt and Waschewsky and the Pratte and Rossi results.

- 115. HOBr + NaBr and KBr.** Mochida et al.<sup>6</sup> studied the uptake of HOBr on solid KBr using multi-layer powders and spray-deposited films in a Knudsen cell. After correction (by factors of ~4–5) for diffusion into the underlying layers for the powders, they obtained values for the initial uptake coefficient in the range of  $(1.3\text{--}8.4) \times 10^{-2}$ , with the corrected values again decreasing with increasing concentrations of HOBr due to the self-reaction of HOBr on the surface:  $2 \text{ HOBr} \rightarrow \text{Br}_2 + \text{H}_2\text{O} + \frac{1}{2} \text{O}_2$ . On spray-deposited films where correction for diffusion into the underlying layers is not necessary, a value of  $0.18 \pm 0.04$  was measured. The recommended upper limit is based on their extrapolation back to very low HOBr concentrations for the powders, and the spray-deposited film results. Br<sub>2</sub> was the only product observed. Chu et al.<sup>2</sup> measured the uptake of HOBr on NaBr at 250 K in a flow tube at RH from 0.5 to 12 %. After correction by approximately an order of magnitude for diffusion of HOBr into the underlying salt layers using a pore diffusion model, a value for  $\gamma_0$  of  $2.5 \times 10^{-3}$  was obtained; the smaller value may be due to the much lower temperature at which these studies were carried out. Again, Br<sub>2</sub> was the only product observed.

The uptake of HOBr on aqueous solutions of NaBr has been measured by Wachsmuth et al.<sup>7</sup> and by Fickert et al.<sup>3</sup> Wachsmuth et al.<sup>7</sup> report a rapid rate of uptake that is limited by mass accommodation; the mass accommodation coefficient was calculated to be  $0.6 \pm 0.2$ . This is consistent with the studies of Fickert et al.<sup>3</sup> who reported a lower limit for the mass accommodation coefficient of  $1 \times 10^{-2}$  at 274 K and observed that Br<sub>2</sub> was released at 100% yield at pH < 6.5. The yield of Br<sub>2</sub> decreased rapidly with pH at higher pH values due to the declining ratio of HOBr to BrO<sup>-</sup>. Fickert et al.<sup>3</sup> also measured the uptake of HOBr on aqueous solutions containing mixtures of NaCl and NaBr. BrCl was the major product at small Br<sup>-</sup> concentrations while Br<sub>2</sub> dominated as the bromide ion concentration in solution increased.

Finally, there have been a number of coated-wall flow tube studies of HOBr reactivity on frozen salt solutions containing both NaCl and NaBr (Kirchner et al.,<sup>5</sup> Huff and Abbatt,<sup>4</sup> and Adams et al.<sup>1</sup>). HOBr uptake coefficients are in the  $10^{-2}$  to  $10^{-3}$  range at roughly 233 K. A general finding is that if the HOBr concentrations are too high, then only BrCl is seen as a gas-phase product from films composed of the (low) seawater ratios of bromide to chloride. The reason for this is that the small concentrations of bromide at the surface are rapidly depleted, leaving only chloride available for reaction. However, for low

HOBr concentrations ( $10^9$  to  $10^{10}$  molecules/cm<sup>3</sup>), as used by Adams et al., Br<sub>2</sub> is observed as the initial product.

**117. BrNO<sub>2</sub> + KCl and NaCl.** Caloz et al.<sup>1</sup> measured an uptake coefficient for BrNO<sub>2</sub> on KCl of  $5 \times 10^{-2}$ , but concluded that it was due only to reaction with a small bromide impurity in the KCl; as expected if this is the case, only Br<sub>2</sub> was generated in the reaction.

The uptake of BrNO<sub>2</sub> on aqueous solutions of 0.5 M NaCl has been measured using a droplet train flow reactor by Schweitzer et al.<sup>3</sup> from 277–293 K yielding  $\gamma_0 \sim 1 \times 10^{-5}$ . Fenzel et al.<sup>2</sup> used a wetted wall flow tube to obtain a lower limit for the uptake coefficient of  $3.8 \times 10^{-5}$  at 291 K.

**118. BrNO<sub>2</sub> + KBr, NaBr and NaI.** Caloz et al.<sup>1</sup> used a Knudsen cell to study the uptake of BrNO<sub>2</sub> on solid KBr powders. The uptake was fast,  $\gamma_0 \geq 0.3$ , with production of Br<sub>2</sub> as the gas phase product.

On aqueous solutions of NaBr, the uptake coefficient increases as the concentration of NaBr increases.<sup>2-4</sup> For example, at 278 K,  $\gamma_0$  increased from  $8.6 \times 10^{-6}$  to  $1.1 \times 10^{-4}$  as the NaBr concentration increased from  $5 \times 10^{-4}$  to  $5 \times 10^{-2}$ , but was independent of temperature over the range from 275–293 K.<sup>4</sup> The major gas phase product is Br<sub>2</sub>, with smaller amounts of BrNO<sub>2</sub> and only at the smaller concentrations of NaBr.<sup>3,4</sup>

The uptake of BrNO<sub>2</sub> on aqueous NaI solutions has been determined using a droplet train flow reactor<sup>3</sup> and a wetted wall flow tube,<sup>4</sup> the uptake coefficient from  $4.4 \times 10^{-5}$  to  $4.4 \times 10^{-4}$  as the iodide concentration increased from  $10^{-4}$  M to  $5 \times 10^{-3}$  M.<sup>4</sup>

**119. BrONO<sub>2</sub> and BrONO<sub>2</sub> + HCl + H<sub>2</sub>O(s).** Hanson and Ravishankara<sup>3</sup> investigated these reactions in an ice-coated flow reactor at 200 ( $\pm 10$ ) K. The reaction of BrONO<sub>2</sub> with H<sub>2</sub>O(s) proceeded at a rate indistinguishable from the gas phase diffusion limit, implying that the reaction probability may be as high as one; the product BrNO(g) was observed. Allanic et al.<sup>2</sup> used a Knudsen cell reactor to measure BrONO<sub>2</sub> uptake between 190–200 K. Values of initial  $\gamma$ 's in the 0.2–0.3 range were observed. An average  $\gamma = 0.26 \pm 0.05$  was obtained from all of the appropriate data from both experiments. Aguzzi and Rossi<sup>1</sup> studied the hydrolysis reaction on various types of ices, obtaining  $\gamma = 0.34 \pm 0.03$  at 180 K and  $\gamma = 0.15 \pm 0.01$  at 210 K. They observed HOBr as the main product and Br<sub>2</sub>O as a secondary product. Hanson and Ravishankara<sup>3</sup> also codeposited HCl with BrONO<sub>2</sub> observing rapid production of BrCl. It is unclear whether BrCl is produced directly from BrONO<sub>2</sub> + HCl or via HOBr (from BrONO<sub>2</sub> hydrolysis) reacting with HCl.

**120. BrONO<sub>2</sub> + H<sub>2</sub>O(l).** Deiber et al.<sup>1</sup> used a droplet train reactor to measure to uptake of BrONO<sub>2</sub> on pure water between 272 and 280 K. An apparent positive temperature dependence was observed with measured reactive uptake measurements ranging from  $0.024 \pm 0.0008$  at 272.5 K to  $0.039 \pm 0.0012$  at 279.7 K.

[Back to Table](#)

**121. BrONO<sub>2</sub> and BrONO<sub>2</sub> + HCl + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Hanson and co-workers used both coated flow tube and aerosol flow tube techniques to show that the reaction of BrONO<sub>2</sub> with 45–70 wt% H<sub>2</sub>SO<sub>4</sub> is extremely facile at temperatures from 210 to 298 K. Hanson and Ravishankara<sup>2</sup> measured  $\gamma$ s of 0.5 (+0.5, -0.25) (45 wt% H<sub>2</sub>SO<sub>4</sub>, 210 K, 0.4 (+0.6, -0.2) (60 wt%, 210 K), and 0.3 (+0.7, -0.1) (70 wt%, 220 K) in a coated-wall flow tube experiment. Hanson et al.,<sup>3</sup> measured  $\gamma \sim 0.8$  (20 to 40% error) for submicron aerosols at temperatures between 249 and 298 K and H<sub>2</sub>SO<sub>4</sub> concentrations of 45 to 70 wt%; there was a sharp fall off in  $\gamma$  for H<sub>2</sub>SO<sub>4</sub> concentrations between 73 and 83 wt%. Hanson also reported additional temperature dependent (230–295 K) coated flow reactor and room temperature (295–300 K) aerosol flow reactor studies extending measurements to higher acid wt% values.<sup>1</sup> Hanson has analyzed these combined data sets, the data indicated that  $\gamma$  is a function of sulfuric acid concentration, but independent of temperature. After eliminating one previously reported anomalously low 83 wt% data point Hanson has fit an empirical expression for measured  $\gamma$ s for BrONO<sub>2</sub> + H<sub>2</sub>O in the form of:  $1/\gamma = 1/\alpha + 1/\gamma_{rxn}$ , where  $\gamma_{rxn} = \exp(a+b*wt)$  and  $\alpha = 0.80$ , and  $a = 29.2$ ,  $b = -0.40$ .<sup>1</sup> Using the same approach as detailed in the note for N<sub>2</sub>O<sub>5</sub> uptake on sulfuric acid, the error for BrONO<sub>2</sub> + H<sub>2</sub>O is 27.3% ( $1\sigma$ ), with  $\gamma_m = 26.6\%$  and  $\gamma_d = 6.3\%$ . Addition of excess HCl to 229 K, 40 and 60 wt% H<sub>2</sub>SO<sub>4</sub> aerosols caused an increase in  $\gamma$  to 1.0 and 0.9, respectively.<sup>3</sup>

- 123. BrONO<sub>2</sub> + NaCl.** Aguzzi and Rossi<sup>1</sup> used a Knudsen cell and three types of NaCl samples (powders, spray-deposited and single crystal) to measure the uptake of BrONO<sub>2</sub> and obtained consistent results with  $\gamma_0 = 0.31 \pm 0.12$ . No correction for diffusion into the powders was made because of the high uptake coefficient (see Subsection 5.6). BrCl was the major product,  $80 \pm 20\%$ , with smaller amounts ( $\sim 10\%$ ) of Br<sub>2</sub> and some HCl. Rapid uptake of BrONO<sub>2</sub> of the same magnitude was observed on the unreactive salts NaNO<sub>3</sub> and Na<sub>2</sub>SO<sub>4</sub>, with a Br<sub>2</sub> yield of  $45 \pm 10\%$ ; this uptake and reaction was attributed to the self-reaction of BrONO<sub>2</sub> on the surface to generate Br<sub>2</sub>O which decomposed to Br<sub>2</sub>.
- Deiber et al.<sup>2</sup> studied the uptake of BrONO<sub>2</sub> on water, NaCl and NaBr solutions using a droplet train apparatus from 272–280 K. The uptake coefficient was the same on water and 0.1 M NaCl, where BrCl was observed as the gas phase product. On NaBr, the uptake increased with the square root of the NaBr concentration, from which a value for the mass accommodation coefficient for BrONO<sub>2</sub> of  $0.063 \pm 0.021$  ( $2\sigma$ ) was obtained.

- 124. BrONO<sub>2</sub> + KBr and NaBr.** Aguzzi and Rossi<sup>1</sup> used a Knudsen cell and three types of KBr samples (powders, spray-deposited and single crystal) to measure the uptake of BrONO<sub>2</sub> and obtained consistent results with  $\gamma_0 = 0.33 \pm 0.12$ . No correction for diffusion into the powders was made because of the high uptake coefficient (see Subsection 5.6). Br<sub>2</sub> was the major product, with its yield decreasing as the concentration of BrONO<sub>2</sub> increased; this was attributed to a competition between the reaction of BrONO<sub>2</sub> with KBr and the self-reaction of BrONO<sub>2</sub> on the surface.
- Deiber et al.<sup>2</sup> studied the uptake of BrONO<sub>2</sub> on water, NaCl and NaBr solutions using a droplet train flow reactor from 272–280 K. The uptake coefficient was the same on water and 0.1 M NaCl. On NaBr, the uptake increased with the square root of the NaBr concentration, from which a value for the mass accommodation coefficient for BrONO<sub>2</sub> of  $0.063 \pm 0.021$  ( $2\sigma$ ) was obtained. The gas phase product on the NaBr solution was Br<sub>2</sub>.

- 125. ICl on NaCl/NaBr.** ICl uptake onto acidified and neutral NaCl/NaBr solutions at 274 to 298 K was studied in coated-wall flow tubes. The initial uptake coefficients were in the  $0.6$  to  $3 \times 10^{-3}$  range depending on the experimental system used, for solutions containing bromide; IBr was the gas-phase product observed. In an aerosol flow tube, uptake of ICl onto concentrated NaBr solutions showed uptake coefficients of  $1$  to  $2 \times 10^{-2}$ , which dropped to values of  $10^{-4}$  on sea-salt solution aerosols. IBr was the product of the reaction on NaBr particles, with a yield of 0.6 (Braban et al.<sup>1</sup>).

- 126. HOI on NaCl/NaBr.** HOI uptake on acidified and neutral NaCl/NaBr solutions at 274 K in a wetted-wall flow tube indicate a lower limit for the uptake coefficient of  $2.2 \times 10^{-3}$  (Braban et al.<sup>1</sup>). IBr is identified as the major gas-phase product when the solutions contain bromide to chloride ratios of 1:200, whereas ICl is the product from pure NaCl solutions. HOI uptake on dry and frozen solutions of NaCl and NaBr with chloride to bromide ratios equal to that of seawater were also studied in a coated wall-flow tube. The product ICl is only formed when the surface is depleted of bromide, otherwise IBr forms. Uptake coefficients measured in a flow reactor by Holmes et al.<sup>2</sup> are  $>0.01$  at 243 K on the frozen films and  $>0.01$  at 243 K and 298 K on dry salts. Mossinger and Cox<sup>3</sup> report uptake of HOI onto dry films of NaCl, NaBr and sea salt from 278 to 298 K and measured uptake coefficients of 0.016, 0.034 and 0.061 respectively. The products are ICl, IBr and IC//IBr, respectively.

SO<sub>2</sub> + O<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub>(s).** Usher et al.<sup>1</sup> present Knudsen cell data showing that pretreatment of  $\alpha$ -alumina with SO<sub>2</sub> increases  $\gamma_0$  values for O<sub>3</sub> uptake by 30%; FTIR observations by the same group show that O<sub>3</sub> oxidized surface sulfite and bisulfite formed by SO<sub>2</sub> absorption to sulfate and bisulfate.

- 129. SO<sub>2</sub> on H<sub>2</sub>O<sub>2</sub>/ice.** SO<sub>2</sub> loss on ice surfaces has been observed to proceed when H<sub>2</sub>O<sub>2</sub> is present, making the reaction of potential significance in ice clouds. Clegg and Abbatt<sup>2</sup> have observed this reaction when both SO<sub>2</sub> and H<sub>2</sub>O<sub>2</sub> are delivered from the gas phase in a coated-wall flow tube at 228 K, with H<sub>2</sub>O<sub>2</sub> in excess. For both SO<sub>2</sub> and H<sub>2</sub>O<sub>2</sub> only small fractions of a monolayer are present on the surface during the reaction. It is inferred that the reaction proceeds through the HSO<sub>3</sub><sup>-</sup> intermediate because the reaction rate declines as acidity builds up on the surface from the sulphuric acid product, i.e., because dissociation of adsorbed SO<sub>2</sub> to form HSO<sub>3</sub><sup>-</sup> is becoming inhibited. At about 200 K, relative to the uptake on pure ice, Chu et al.<sup>1</sup> observe enhanced loss of SO<sub>2</sub> on ice films that have been doped with 3% H<sub>2</sub>O<sub>2</sub> and they detect sulphate as a product. Uptake coefficients are reported in Clegg and Abbatt that are dependent on both the H<sub>2</sub>O<sub>2</sub> and SO<sub>2</sub> partial pressure, so no single value prevails for atmospheric conditions.

- (2) Clegg, S. M.; Abbatt, J. P. D. Oxidation of SO<sub>2</sub> by H<sub>2</sub>O<sub>2</sub> on ice surfaces at 228 K: A sink for SO<sub>2</sub> in ice clouds. *Atmos. Chem. Phys.* **2001**, *1*, 73-78.

**130. SO<sub>2</sub> + H<sub>2</sub>O<sub>2</sub>, O<sub>3</sub>, HONO, NO<sub>2</sub>, HNO<sub>3</sub> + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Rattigan et al.<sup>2</sup> used a bubble train reactor to measure the uptake of SO<sub>2</sub> in the presence of solvated oxidants at 293 K. For H<sub>2</sub>O<sub>2</sub> the second order rate constant at 1 wt% H<sub>2</sub>SO<sub>4</sub> agreed well with previous bulk kinetics measurements and with previous droplet train/flow reactor measurements. Measurements at 20, 40, and 60 wt% H<sub>2</sub>SO<sub>4</sub> are the first reported for concentrated acid. Reaction rate data were fit to a two term (acid catalyzed and water catalyzed) bulk second order rate expression, which, in the limit of high acid activity ( $a_{H^+} = \alpha_{H^+}[H^+]$ , where  $\alpha_{H^+}$  is the H<sup>+</sup> activity coefficient) reduces to:  $k^{II}_{H_2O_2} = 8.3 \times 10^4 (\alpha_{H_2O}/a_{H^+})$ , where  $\alpha_{H_2O}$  is the water activity coefficient. Both  $\alpha_{H^+}$  and  $\alpha_{H_2O}$  can be obtained from the sulfuric acid thermodynamic model of Carslaw et al.<sup>1</sup> The high  $a_{H^+}$  approximation for  $k^{II}_{H_2O_2}$  should be accurate to a factor of two between 40 and 70 wt%. Uptake of SO<sub>2</sub> in the presence of solvated O<sub>3</sub> was measured for 1–70 wt% acid; the Henry's law expression for O<sub>3</sub> was determined in separate experiments. Measured second order rates agree reasonably well with previous results measured below 18 wt%. A three term fit for reaction with SO<sub>2</sub>(aq), HSO<sub>3</sub><sup>-</sup>, and SO<sub>4</sub><sup>=</sup> was fit to the data:  $k^{II}_{O_3} = 6.6 \times 10^3 [SO_2(aq)] + 3.2 \times 10^5 [HSO_3^-] + 1 \times 10^9 [SO_4^=]$ . This expression should be accurate to a factor of two between 20 and 70 wt%.

The HONO reaction was studied by adding nitrosyl sulfuric acid to 20, 40, 60, and 70 wt% acid. Measured second order rate constants were moderately consistent with previous measurements below 10 wt%. A  $k^{II}_{HONO} = 142[H^+]$  was fit to the full data set; it should be accurate to a factor of two for acid concentrations between 10 and 70 wt%.

No enhanced SO<sub>2</sub> uptake was observed with added gas phase NO, NO<sub>2</sub>, or with 20 wt% HNO<sub>3</sub> added to 50–60 wt% sulfuric acid.

**131. SO<sub>2</sub> + Al<sub>2</sub>O<sub>3</sub>.** Goodman et al.<sup>2</sup> used FTIR observations of SO<sub>2</sub> absorption on  $\alpha$ -alumina to show that surface bound sulfite and bisulfite products are produced, they integrated these surface feature absorbencies to estimate a  $\gamma_0$  of  $(9.5 \pm 0.3) \times 10^{-5}$ . Usher et al.<sup>8</sup> performed BET corrected room temperature studies on four  $\alpha$ -alumina samples reporting an average  $\gamma_0$  of  $(1.6 \pm 0.5) \times 10^{-4}$ . Seisel et al.<sup>7</sup> measured  $\gamma_0 = (7.4 \pm 0.9) \times 10^{-3}$  on  $\gamma$ -alumina at 298 K using a pulsed Knudsen cell method. FTIR studies of SO<sub>2</sub> uptake on commercial  $\gamma$ -alumina catalyst samples also show sulfite formation on non-hydroxylated surfaces.<sup>1,3</sup> Ma et al.<sup>6</sup> co-deposited SO<sub>2</sub> and NO<sub>2</sub> on  $\gamma$ -alumina surfaces, using FTIR to observe that rather than forming adsorbed nitrite or nitrate, NO<sub>2</sub> dimerized and the dimer oxidized SO<sub>2</sub> to sulfate. Ma and coworkers<sup>4</sup> extended their studies of NO<sub>2</sub>/N<sub>2</sub>O<sub>4</sub> interactions with adsorbed SO<sub>2</sub> on  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>, CaO,  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>, ZNO<sub>3</sub>, MgO, TiO<sub>2</sub> and SiO<sub>2</sub>. Lo et al.<sup>5</sup> published a density functional theory study of SO<sub>2</sub> interactions with hydrated and dehydrated  $\gamma$ -alumina surfaces calculating the thermochemistry of SO<sub>2</sub> adsorption and conversion to SO<sub>3</sub>/HSO<sub>3</sub>.

**132. SO<sub>2</sub> + NaCl and sea salt.** Gebel et al.<sup>1</sup> reported no measurable uptake of SO<sub>2</sub> on NaCl, yielding an upper limit of  $1 \times 10^{-4}$  for the uptake coefficient. The same was true for synthetic sea salt that had been heated while pumping. However, sea salt that had not been heated or pumped on extensively had a rapid uptake of SO<sub>2</sub>, with initial uptake coefficients as large as 0.09. The time dependence of the uptake coefficient was consistent with uptake of SO<sub>2</sub> into a liquid layer, likely due to large amounts of water adsorbed on the hygroscopic components of sea salt such as magnesium hydrate. No gas phase products were observed but sulfite formation in the salt was seen by FTIR, indicating that uptake was due to dissolution of SO<sub>2</sub> into the water film on the salt surface.

**133. SO<sub>3</sub> + H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Jayne et al.<sup>1</sup> measured the uptake coefficient in a wetted wall-flow reactor at 300 K over a composition range of 78–92 H<sub>2</sub>SO<sub>4</sub> wt%. The measured  $\gamma$  was indistinguishable from 1.0. Higher water concentrations and lower temperatures probably tend to increase  $\gamma$ , so a value near 1.0 probably holds for all atmospheric conditions.

Phys. Chem. A* **1997**, *101*, 10000-10011.

**134. OCS + Al<sub>2</sub>O<sub>3</sub>.** Liu and co-workers have measured OCS uptake on both  $\alpha$ -alumina and  $\gamma$ -alumina surfaces at 298 K using Knudsen cell techniques<sup>3</sup> and on  $\alpha$ -alumina surfaces with controlled water vapor levels using both a Knudsen cell and a reaction chamber equipped with diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS).<sup>4</sup> The DRIFTS technique was also used to investigate heterogeneous reaction mechanisms, revealing that surface Al-OH plays a major role in oxidizing adsorbed OCS to CO<sub>2</sub> and that a number of surface adsorbed reactive intermediate anions, including HSCO<sub>2</sub><sup>-</sup>, are formed. The overall reaction is essentially a surface catalyzed hydrolysis reaction producing both CO<sub>2</sub> and H<sub>2</sub>S.<sup>1,2,4</sup> Liu et al.<sup>3</sup> report uptake of relatively dry OCS yielding rather small  $\gamma_0 = (4.9 \pm 0.5) \times 10^{-7}$  and  $\gamma_{ss} = (6.5 \pm 2.4) \times 10^{-8}$  values for  $\alpha$ -alumina and  $\gamma_0 = (1.0 \pm 0.2) \times 10^{-7}$  and  $\gamma_{ss} = (1.8 \pm 0.4) \times 10^{-8}$  values for  $\gamma$ -alumina at 298 K. The low steady-state uptake coefficients are probably due to consumption of most of the surface Al-OH sites and a low regeneration rate due to limited water vapor. OCS uptake experiments that provide controlled water vapor fluxes to  $\alpha$ -alumina surfaces produce somewhat higher  $\gamma_{ss}$  values in the Knudsen apparatus, and the values obtained by integrating the DRIFTS spectra for RH values between 7 and 47% fall in the range of  $7.4 \times 10^{-6}$  to  $3.3 \times 10^{-6}$ .<sup>4</sup> Interestingly, the highest uptake values are not obtained for the highest RH values because water vapor can also occupy reactive alumina surface sites and block OCS adsorption.

## 5.16 Notes to Table 5-3

1. See the discussions on soot presented in the introductory discussions of “Surface Types” and “Parameter Definitions” for descriptions of some of the factors affecting the uptake and reaction of gases on soot surfaces. In most cases, the available reactive surface area rather than the geometric areas have been used in obtaining the uptake coefficients; in those cases where the geometric area was used but a higher available surface area was involved in the measured uptake, the uptake coefficient is given as an upper limit. Most data are available at room temperature or there are very limited data at lower temperatures characteristic of the upper troposphere.

[Back to Table](#)

2. **SO<sub>2</sub> + soot.**  $\gamma \leq 3 \times 10^{-3}$  measured using Degussa FW2 carbon black by Rogaski et al.<sup>7</sup> This is an upper limit since it is based on the geometric surface area. Koehler et al.<sup>5</sup> measured an average value of  $(2 \pm 1) \times 10^{-3}$  over the first 10–30 s on n-hexane soot at –100° C (the initial uptake may be larger), but indicate that taking into account surface roughness would reduce this value. A number of studies<sup>1–7</sup> suggest that uptake is primarily due to physisorption on the surface; oxidation occurs in the presence of water, oxidants and metals.

3. **NH<sub>3</sub> + soot.** Chughtai et al.<sup>1</sup> and Muenter and Koehler<sup>2</sup> measured the uptake of NH<sub>3</sub> on soot. Based on Muenter and Koehler<sup>2</sup> where conditions are closest to atmospheric, NH<sub>3</sub> is not taken up by soot particles at temperatures above 173 K.

- 4. O<sub>3</sub> + soot.** Many studies report a rapid, initial loss of O<sub>3</sub> followed by a slower loss that also occurs on aged soot or soot pre-exposed to ozone<sup>2,4-10,13,14,17,18</sup>. Initial, rapid O<sub>3</sub> loss may be most applicable for soot as it comes out of aircraft exhaust, with  $\gamma^{\text{init}} \sim 10^{-3}$  from most studies using both carbon black and organic combustion soots.<sup>6-8,13,18</sup> The second stage of the reaction is probably more applicable to soot dispersed in air;  $\gamma^{\text{aged}} \sim 10^{-4}-10^{-6}$  using both carbon black and organic combustion soots,<sup>6-10,12,18</sup> but in the range of 10<sup>-4</sup> to 10<sup>-5</sup> based on organic combustion soot data alone.<sup>8,10</sup> A few studies have been carried out at temperatures below room temperature,<sup>2,8-10</sup> given the wide ranges measured even at room temperature, these values generally fall in the same range. Il'in et al.<sup>8</sup> report a temperature dependence for the initial uptake on fresh soot of  $\gamma^{\text{fresh}} = 1.9 \times 10^{-3} \exp(-780/T)$  and for aged soots,  $\gamma^{\text{aged}} = 1.8 \times 10^{-4} \exp(-1000/T)$ . Both physisorption and reaction of ozone with the surface appear to take place. The studies of Fendel et al.<sup>6</sup> suggest that lower particle growth in size below 40 ppb O<sub>3</sub> is due to less than a monolayer of O<sub>3</sub> on the surface. Stephens et al.<sup>18</sup> proposed a Langmuir-type reversible adsorption of O<sub>3</sub>, followed by a slower reaction with the surface. Pöschl et al.<sup>12</sup> proposed a similar scheme for uptake of ozone on spark-generated graphite soot coated with benzo[a]pyrene. Initial reversible physisorption occurred with  $\gamma \sim 10^{-3}$ , and “apparent reaction probabilities” for O<sub>3</sub> with BaP on soot of  $\gamma \sim 10^{-5}-10^{-6}$  were reported. The presence of water inhibited the reaction, which was postulated to be due to competitive adsorption between water and ozone on the surface; this is in contrast to the report of Chughtai et al.<sup>1</sup> in which the rate of ozone loss increased with RH. Pöschl et al.<sup>12</sup> report Langmuir adsorption equilibrium constants for O<sub>3</sub> and H<sub>2</sub>O, and a second order surface reaction rate constant for the O<sub>3</sub>-BaP reaction of  $(2.6 \pm 0.8) \times 10^{-17} \text{ cm}^{-2} \text{ s}^{-1}$ . Three possible paths have been proposed: (1) chemisorption of O<sub>3</sub>; (2) catalytic decomposition of O<sub>3</sub>:  $2\text{O}_3 \rightarrow 3\text{O}_2$ ; (3) surface oxidation and formation of gas-phase carbon oxides. The studies of Fendel et al.<sup>6</sup> suggest that lower particle growth in size below 40 ppb O<sub>3</sub> is due to less than a monolayer of O<sub>3</sub>. Studies of Smith et al.<sup>17</sup> and Smith and Chughtai<sup>14</sup> suggest that catalytic decomposition occurs to some extent over the entire reaction sequence. CO<sub>2</sub> and H<sub>2</sub>O are the major gas phase and surface oxidized functional groups on the surface such as carboxylic acids are observed.<sup>1-3,5,6,9,11,14-16,18</sup>

- 5. HNO<sub>3</sub> + soot.** Studies of the uptake of HNO<sub>3</sub> on soot have been carried out over a range of nitric acid pressures.<sup>1-8</sup> Measured values of  $\gamma$  at room temperature are typically in the range 10<sup>-1</sup>-10<sup>-5</sup>, with smaller uptake coefficients measured at longer reaction times. Saathoff et al.<sup>7</sup> report an upper limit of  $3 \times 10^{-7}$  as a time-averaged value over two days. At lower concentrations characteristic of the atmosphere, uptake appears to be primarily due to physisorption while at higher concentrations,  $>2 \times 10^{12}$  molecule cm<sup>-3</sup>, a surface reaction occurs. At 220 K,  $\gamma \sim 0.1$  with irreversible uptake attributed to reaction with surface groups.<sup>1</sup> Reaction of HNO<sub>3</sub> at concentrations from  $(1-9) \times 10^{12}$  molecule cm<sup>-3</sup> with "grey" soot from a rich flame using hexane has been reported<sup>8</sup> to generate HONO as the major gaseous product with initial and steady-state reaction probabilities of  $\gamma_0 = 4.6 \times 10^{-3}$  and  $\gamma_{ss} = 5.2 \times 10^{-4}$ , respectively; reaction with "black" soot from a lean flame gave NO as the major gaseous product, with initial and steady-state reaction probabilities of  $\gamma_0 = 2.0 \times 10^{-2}$  and  $\gamma_{ss} = 4.6 \times 10^{-3}$ , respectively (based on geometric surface area of sample holder). The NO was hypothesized to result from secondary reactions of an initial HONO product.

- 6. N<sub>2</sub>O<sub>5</sub> + soot.** Brouwer et al.,<sup>1</sup> Longfellow et al.,<sup>2</sup> and Saathoff et al.<sup>3</sup> studied the uptake of N<sub>2</sub>O<sub>5</sub> at room temperature on a ground charcoal (carbon black) sample, on propane soot and on spark-generated graphite soot, respectively. Brouwer et al. and Longfellow et al. report uptake coefficients based on the geometric sample surface area, and therefore give upper limits. An upper limit of  $\gamma \leq 0.02$  can be derived based on the

larger value of 0.016 reported by Longfellow et al. As discussed below, much smaller values are reported by Saathoff et al.:  $4 \times 10^{-5}$  under dry conditions and  $2 \times 10^{-4}$  at 50% RH. Three possible reactions may occur: (1) decomposition of  $\text{N}_2\text{O}_5$  on the surface to generate  $\text{NO}_2 + \text{NO}_3$ ; (2) reaction of  $\text{N}_2\text{O}_5$  with the soot; (3) hydrolysis of  $\text{N}_2\text{O}_5$  with water on the surface to generate  $\text{HNO}_3$ . The studies of Longfellow et al. support the decomposition reaction, with yields of  $\text{NO}_2$  within experimental error of 100%; the generation of  $\text{NO}_3$  on the surface followed by its decomposition to  $\text{NO}_2$ , may contribute to the observed production of  $\text{NO}_2$ . The studies of Brouwer et al. suggest that a redox reaction with the soot surface to generate  $\text{NO}$  occurs in parallel with hydrolysis of  $\text{N}_2\text{O}_5$  to generate  $\text{HNO}_3$ . Saathoff et al. propose two independent, parallel reactions: (1) hydrolysis generating  $\text{HNO}_3$ ,  $\text{N}_2\text{O}_5 + \text{soot} \rightarrow 2 \text{HNO}_3$  with  $\gamma = (4 \pm 2) \times 10^{-5}$  under dry conditions ( $< 10 \text{ ppm H}_2\text{O}$ ) which increases to  $(2 \pm 1) \times 10^{-4}$  at 50% RH. (2) decomposition to  $\text{NO}$  and  $\text{NO}_2$ :  $\text{N}_2\text{O}_5 + \text{soot} \rightarrow \text{NO} + \text{NO}_2 + \text{products}$ , with  $\gamma = (4 \pm 2) \times 10^{-6}$  under dry conditions.

Lett.* **2001**, *28*, 1957-1960.

7.  **$\text{NO}_2 + \text{soot}$ .** A fast initial uptake of  $\text{NO}_2$  is observed on fresh soots<sup>1-3,8-12,15,17,19,20,24-26</sup> with the initial uptake coefficient in studies involving both carbon blacks and organic combustion soots in the range of  $\gamma^{\text{init}} \geq 10^{-1}$  to  $10^{-4}$ . For longer reaction times on carbon black soots,  $\gamma^{\text{aged}} \sim 10^{-4}$  based on studies by Kalberer et al.<sup>16</sup> and Ammann et al.<sup>3,4</sup> However, Kleffmann et al.<sup>18</sup> report a lower uptake coefficient of  $\sim 10^{-7}$  on carbon black over the first 5 minutes of reaction and Saathoff et al.<sup>21</sup> report an upper limit of  $< 4 \times 10^{-8}$  averaged over 5 days under dry conditions ( $< 10 \text{ ppm H}_2\text{O}$ ) on spark-generated graphite. On organic combustion soots,  $\gamma^{\text{aged}}$  has been reported to be in the range of  $\sim 10^{-4}-10^{-6}$ .<sup>1,4,5,19,22,24</sup> All studies were done at room temperature except those of Longfellow et al.<sup>19</sup> which were carried out at 262 K. The surface deactivates on continued exposure to  $\text{NO}_2$ , suggesting a maximum amount of HONO that can be formed per  $\text{cm}^2$  of soot area or mg of soot; this has been reported to be in the range of  $10^{16}$  to  $10^{18}$  HONO per mg of soot.<sup>5,12,14,15,18,24</sup> However, reactivation on heating of the surface, exposure to water vapor and/or with time after the exposure is stopped has been observed.<sup>12,19,24-26</sup> A small portion (~10–20%) of the  $\text{NO}_2$  taken up appears to be chemisorbed to the surface.<sup>1,5,9,14,15,17,18,24-26</sup> Infrared studies<sup>1,17,23</sup> show that surface C–ONO, C–N–NO<sub>2</sub>, and C–NO<sub>2</sub> groups are formed. The remainder of  $\text{NO}_2$  reacted appears as gaseous HONO and NO; Salgado and Rossi<sup>22</sup> report HONO as the major product for hexane soot from a flame at near stoichiometric ratio but NO as the major product for soot from an extremely lean flame. In addition,  $\text{N}_2\text{O}$ , CO, and  $\text{CO}_2$  have been observed as products at higher temperatures.<sup>6,7</sup> At lower  $\text{NO}_2$  concentrations, the HONO yield can approach 100%; production of NO may be due to the bimolecular reaction of HONO on the surface at higher concentrations to give  $\text{NO} + \text{NO}_2 + \text{H}_2\text{O}$ . The HONO yield at 262 K appears to be smaller than at room temperature.<sup>19</sup> Formation of HONO is due to reaction with a reduced surface site and not to  $\text{NO}_2$  surface-catalyzed hydrolysis. The formation of HONO from the reaction of  $\text{NO}_2$  with unspecified semi-volatile organics in diesel exhaust has been reported<sup>13</sup> and proposed to be a much larger source of HONO than the reaction with the soot itself.

- 11. H<sub>2</sub>O + soot.** Alcala-Jornod et al.<sup>1</sup> report an upper limit to the initial uptake coefficient of  $\gamma < 2 \times 10^{-3}$ , consistent with the earlier measurements of Rogaski et al.<sup>8</sup> The uptake is most likely a reversible physisorption<sup>1,7</sup> although based on water uptake isotherms, Chughtai et al.<sup>2,3,5,6</sup> propose that at low relative humidities (<25%) chemisorption occurs. While prior exposure of Degussa FW-2 to NO<sub>2</sub> and SO<sub>2</sub> was not found to increase the uptake coefficient for water, treatment with HNO<sub>3</sub> increased the measured uptake coefficient by a factor of 28 and with H<sub>2</sub>SO<sub>4</sub> by a factor of 68.<sup>8</sup> Water adsorption isotherms on soot have been measured in a number of studies, e.g.<sup>2-6</sup> and the amount of water taken up found to increase with the air/fuel ratio used to generate the soot, with the sulfur content, with aging and oxidation of the surface (e.g. by O<sub>3</sub>) and with the presence of metals.<sup>2-6,9</sup>

a. ln H = A + B/T + C ln(T) [M atm<sup>−1</sup>]

b. Uncertainty Classes:

- I—Better than 10%
- II—10% to 50%
- III—50% to 100%
- IV—Factor of 2 to factor of 10
- V—Factor of 10 to factor of 100
- VI—Greater than a factor of 100

c. h<sub>G,0</sub> and h<sub>T</sub> are the gas-specific Sechenov coefficients. See section 5.10, Parameter Definitions, for more information.

## 5.18 Notes to Table 5-4

### Note 1: Simple O, H Species

[Back to Table](#)

<b>O<sub>2</sub></b>	The recommendation was taken from the studies of Benson et al. <sup>1</sup> and Rettich et al. <sup>9</sup> The data show clear curvature in a plot of $\ln(K_h)$ v. $1/T$ . A two parameter fit gives $A = -13.26$ and $B = 1950$ K for the temperature range 273–285 K. The salt effect parameter $h_{G,o}$ is set to zero (see discussion in the text preceding this Table). The temperature dependent salt effect parameter is from the optimization of Weisenberger and Schumpe. <sup>16</sup>
<b>O<sub>3</sub></b>	The recommendation of Rischbieter et al. <sup>10</sup> was accepted and refitted. Salt effect parameters were obtained from the effect of NaCl, KCl, Na <sub>2</sub> SO <sub>4</sub> , and Ca(NO <sub>3</sub> ) <sub>2</sub> on H, combined with specific ion parameters.
<b>H</b>	An average of estimates of the solubility of H based on two approaches: One is simply the assumption that the solubility of H is the same as the solubility of H <sub>2</sub> . <sup>8</sup> The second assumes that the solubility of H is what would be expected for a rare gas atom of the same radius. <sup>11</sup> The average value from 273 K to 298 K is $2.6 \times 10^{-4}$ , with very small variation with temperature. Above room temperature the solubility increases.
<b>OH</b>	Calculated from the reduction potential of the OH radial, $E^\circ(OH/OH^-) = (1.90 \pm 0.02)$ V, derived from an equilibrium with Tl <sup>+</sup> . <sup>13</sup> This was combined with the Gibbs energy of the anion and the gas-phase radical to obtain the free energy of solution.
<b>HO<sub>2</sub></b>	The recommendation was based on a calculation by Schwartz <sup>12</sup> based on the gas phase constituents HO <sub>2</sub> , H <sup>+</sup> , and O <sub>2</sub> <sup>-</sup> . Thermodynamic values were updated to those in our Thermodynamic tables, to $pK_a = (4.8 \pm 0.1)$ , and to a reduction potential $E^\circ(O_2/O_2^-) = -(0.35 \pm 0.01)$ V. The reduction potential, referenced to one atmosphere O <sub>2</sub> , is based primarily on equilibria reported by Meisel and Czapski, <sup>6</sup> corrected for a revised duroquinone potential. <sup>15</sup>
<b>H<sub>2</sub>O<sub>2</sub></b>	The data of Lind and Kok <sup>4</sup> (corrected), <sup>5</sup> Hwang and Dasgupta, <sup>3</sup> Yoshizumi et al., <sup>17</sup> Staffelback and Kok, <sup>14</sup> O'Sullivan et al., <sup>7</sup> and Huang and Chen <sup>2</sup> are all in good agreement. The recommendation is from a two-parameter fit to all the results (Kok, et al. and Hwang and Dasgupta are represented by calculated endpoints; Huang and Chen by calculated points at the experimental temperatures). Previous recommendations were $A = -14.16$ and $B = 760$ .

**Note 2: Simple Inorganic Nitrogen Species**

[Back to Table](#)

<b>N<sub>2</sub></b>	The recommendation of Battino <sup>3</sup> was accepted and refitted to three-parameter equations. A two parameter fit gives A = 12.81 and B = 1625 K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>18</sup>
<b>NH<sub>3</sub></b>	Based on the recommendation by Edwards et al., <sup>9</sup> refit to a two-parameter equation. Over the temperature range 273–348 K, there appears to be little curvature in the data. The more recent work of Dasgupta and Dong <sup>8</sup> are in quite good agreement with this recommendation, whereas the results of Hales and Drewes <sup>10</sup> are somewhat higher and those of Shi et al. <sup>16</sup> (an uptake study) are significantly lower. The Hales and Drewes paper also included studies of the effect of dissolved CO <sub>2</sub> on the solubility of NH <sub>3</sub> . The solubility of NH <sub>3</sub> in solutions containing a wide variety of ions is discussed by Clegg and Brimblecombe. <sup>7</sup> Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>18</sup>
<b>NF<sub>3</sub>, N<sub>2</sub>F<sub>4</sub></b>	Refit to three- parameter equation from the recommendation of Wilhelm et al. <sup>19</sup>
<b>Chloramines</b>	Derived from flashoff studies with glass sparging columns at 20°C and 40°C. <sup>11</sup> Data point for ammonia at 20°C in exact agreement with recommended value in Table.
<b>NO</b>	Three-parameter refit from the recommendation of Battino. <sup>2</sup> Two-parameter fit gives A = -12.27 and B = 1790 K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>18</sup>
<b>NO<sub>2</sub></b>	Based on NO <sub>2</sub> uptake studies and an analysis of literature values. <sup>6</sup> A value of 0.014 was obtained from an analysis of studies of reactive dissolution of NO <sub>2</sub> by Schwartz and White. <sup>15</sup>
<b>NO<sub>3</sub></b>	From the reduction potential E°(NO <sub>3</sub> /NO <sub>3</sub> <sup>-</sup> ) = (2.46 ± 0.02) V, which is an average based on determinations of equilibria with Cl <sup>-</sup> , <sup>5,12</sup> combined with the Gibbs energy for the anion and the gas-phase radical. The derived solubility value is in good agreement with that calculated from the uptake of NO <sub>3</sub> into a wetted-wall flow reactor containing Cl <sup>-</sup> . <sup>13</sup> It is in very poor agreement with the much higher value derived from a study of the uptake of NO <sub>3</sub> by a series of wetted denuders. <sup>17</sup>
<b>N<sub>2</sub>O</b>	Three-parameter refit to the recommendation of Battino. <sup>1</sup> Two parameter fit gives A = 13.40 and B = 2880 K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>18</sup>

<b>NOCl</b>	Uptake kinetics measured as function of temperature into water and solutions containing HCl, NaCl, and NaOH. Only the latter had an effect. The kinetics were consistent with an uptake coefficient of 0.03. <sup>14</sup>
<b>HN<sub>3</sub></b>	Measured using a packed column technique at pH 1.8 ( $\mu = 0.02 \text{ mol L}^{-1}$ ). The effective Henry's law constant can be calculated using $K_H^* = K_H(1 + K_a/[H^+])$ , with $pK_a = 4.65^4$

**Note 4: Hydrocarbons**[Back to Table](#)

<b>CH<sub>4</sub></b>	The recommendation is a three-parameter fit to the smoothed recommendation of Battino. <sup>1</sup> There is very good agreement with the more recent data of Ben-Naim and Battino. <sup>2</sup> A two parameter fit gives $A = -13.45$ and $B = 2040$ K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>4</sup>
<b>C<sub>2</sub>H<sub>6</sub></b>	The recommendation is a three-parameter fit to the smoothed recommendation of Battino. <sup>1</sup> There is very good agreement with the more recent data of Ben-Naim and Battino. <sup>2</sup> Two parameter fit gives $A = -15.95$ and $B = 2875$ K for the temperature range 273–293 K.
<b>C<sub>3</sub>H<sub>8</sub></b>	The recommendation is a three-parameter fit to the smoothed recommendation of Battino. <sup>1</sup> There is very good agreement with the more recent data of Ben-Naim and Battino. <sup>2</sup> A two parameter fit gives $A = 17.52$ and $B = 3275$ K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>4</sup>
<b>n-C<sub>4</sub>H<sub>10</sub></b>	The recommendation is a three-parameter fit to the smoothed recommendation of Battino. <sup>1</sup> There is very good agreement with the more recent data of Ben-Naim and Battino. <sup>2</sup> A two parameter fit gives $A = -19.28$ and $B = 3740$ K for the temperature range 273–288 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>4</sup>
<b>CH<sub>3</sub>CH(CH<sub>3</sub>)CH<sub>3</sub></b>	The recommendation is from a three-parameter fit to the smoothed recommendation of Battino. <sup>1</sup> A two parameter fit gives $A = 18.22$ and $B = 3340$ K for the temperature range 278–293 K.
<b>C<sub>2</sub>H<sub>4</sub></b>	The recommendation is from a three-parameter fit to the smoothed recommendation of Wilhelm. <sup>5</sup> A two parameter fit gives $A = -12.40$ and $B = 2170$ K for the temperature range 288–313 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>4</sup>
<b>C<sub>2</sub>H<sub>2</sub></b>	Converted from the evaluation of Fogg et al. <sup>3</sup> A two parameter fit gives $A = -10.70$ and $B = 2230$ for the temperature range 272–298 K. Previous recommendation was from a three-parameter fit to the recommendation of Wilhelm et al. <sup>5</sup> The recommendation of Yaws et al. <sup>6</sup> generates identical results.

[Back to Table](#)

- CH<sub>3</sub>F** A refit to the evaluation of Staudinger and Roberts.<sup>5</sup>
- CH<sub>3</sub>Cl** From the review of Warneck<sup>6</sup> and in good agreement with the review cited previously.<sup>5</sup> The uncertainties quoted are  $\pm 0.47$  in A and  $\pm 139$  in B. A more recent study over the temperature range 8–91°C is also in close agreement, with  $K_h = 0.104$  vs.  $0.131 \text{ M atm}^{-1}$  at 293 K.<sup>3</sup>
- CH<sub>3</sub>Br, CH<sub>3</sub>I** A refit to the evaluation of Staudinger and Roberts.<sup>5</sup>
- CH<sub>2</sub>Cl<sub>2</sub>** From the review of Warneck.<sup>6</sup> The review cited previously,<sup>5</sup> gave somewhat different parameters, but a similar value at 298 K. The uncertainties quoted are  $\pm 0.78$  in A and  $\pm 231$  in B. A more recent study over the temperature range 8–91°C is also in close agreement, with  $K_h = 0.401$  vs.  $0.485 \text{ M atm}^{-1}$  at 293 K.<sup>3</sup>
- CHCl<sub>3</sub>** From the review of Warneck.<sup>6</sup> The review cited previously,<sup>5</sup> gave somewhat different parameters, but a similar value at 298 K. The uncertainties quoted are  $\pm 0.38$  in A and  $\pm 112$  in B. A more recent study over the temperature range 8–91°C is also in close agreement, with  $K_h = 0.313$  vs.  $0.334 \text{ M atm}^{-1}$  at 293 K.<sup>3</sup>
- CHCl<sub>2</sub>Br, CHClBr<sub>2</sub>, CHBr<sub>3</sub>, CF<sub>2</sub>Cl<sub>2</sub>, CFCl<sub>3</sub>** A refit to the evaluation of Staudinger and Roberts.<sup>5</sup>
- CCl<sub>4</sub>** From the review of Warneck<sup>6</sup> and in good agreement with the review cited previously.<sup>5</sup> The uncertainties quoted are  $\pm 0.40$  in A and  $\pm 119$  in B. A more recent study over the temperature range 8–91°C is also in close agreement, with  $K_h = 0.040$  vs.  $0.046 \text{ M atm}^{-1}$  at 293 K.<sup>3</sup>
- CHF<sub>3</sub>** Calculated values from the evaluation of Welhelm<sup>7</sup> were combined with results from Zheng et al.,<sup>8</sup> double weighted. The latter study, gas solubilities measured at 278, 308, and 338 K and at NaCl concentrations from 0 to 0.0564 mole/mole (0 to 174%) with a gas absorption unit. Calculated values for 0% NaCl taken at each temperature and fitted to a two-parameter equation.
- CHF<sub>2</sub>Cl** A linear fit to the data of Zheng et al.,<sup>8</sup> Boggs and Buck,<sup>1</sup> and Kutsuna and Hori.<sup>4</sup> The data of Chang and Criddle<sup>2</sup> were significantly lower than these results and not included in the fit. The review by Wilhelm, et al.<sup>7</sup> gave a three-parameter fit that indicated curvature, but this does not appear to be supported by these more recent data.

[Back to Table](#)

**CH<sub>3</sub>OH** The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.<sup>4</sup> A two-parameter fit up to 298 K gives  $A = -13.61$  and  $B = 5640$ , whereas a two-parameter fit up to 373 K gave  $A = -12.16$  and  $B = 5215$ . An evaluation by Warneck<sup>10</sup> for the temperature range 273 to 353 K resulted in recommended parameters of  $A = -12.45$  and  $B = 5310$ . The previous recommendation was  $A = -12.08$  and  $B = 5210$ , which was based on the two data points of Snider and Dawson.<sup>8</sup> The 298 K result of Butler et al.<sup>3</sup> and a calculation based on the NBS Thermodynamic tables,<sup>9</sup> are in very good agreement. The 298 K result of Altschuh et al.<sup>1</sup> is about 40% lower.

**C<sub>2</sub>H<sub>5</sub>OH** The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.<sup>4</sup> A two-parameter fit up to 298 K gives  $A = -17.14$  and  $B = 6660$ , whereas a two-parameter fit up to 373 K gave  $A = -14.57$  and  $B = 5908$ . An evaluation by Warneck<sup>10</sup> for the temperature range 273 to 353 K resulted in recommended parameters of  $A = -15.87$  and  $B = 6274$ . The previous recommendation was  $A = -16.98$  and  $B = 6630$ , which was based on the two data points of Snider and Dawson,<sup>8</sup> the 298 K results of Butlar, et al.<sup>3</sup> and Rohrschneider,<sup>7</sup> and a calculation based on the NBS Thermodynamic tables,<sup>9</sup> are in very good agreement. The 298 K result of Altschuh, et al.<sup>1</sup> is about 50% lower.

**n-C<sub>3</sub>H<sub>7</sub>OH** The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.<sup>4</sup> A two-parameter fit up to 298 K gives A = -19.80 and B = 7370. The previous recommendation was A = -20.16 and B = 7470, which was based on two data points from Snider and Dawson.<sup>8</sup> Room temperature data from other studies<sup>1-3</sup> support these results.

**iso-C<sub>3</sub>H<sub>7</sub>OH, 2-propanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.<sup>5</sup> A two-parameter fit up to 298 K gives A = -18.95 and B = 7100. The previous recommendation was A = -20.5 and B = 7450, which was based on the two data points of Snider and Dawson<sup>8</sup> supported by room temperature data from other studies.<sup>1,3</sup>

**n-C<sub>4</sub>H<sub>9</sub>OH** The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.<sup>4</sup> A two-parameter fit up to 298 K gives A = -17.68 and B = 6725. The previous recommendation was A = -19.34 and B = 72.10, which was based on two data points from Snider and Dawson.<sup>8</sup> Room temperature data from other studies<sup>1,2</sup> support these results.

**iso-C<sub>4</sub>H<sub>9</sub>OH, 2-methyl-1-propanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants, over the temperature range 298–372 K.<sup>5</sup> A two-parameter fit up to 298 K gives A = -21.56 and B = 7720. Extrapolated values are in very good agreement with the results of Snider and Dawson<sup>8</sup> at 273 and 298 K and room temperature data from other studies.<sup>3,1</sup> A room temperature value of 22.2 M atm<sup>-1</sup> from a thermal desorption-GC/MS study is about 40% lower than this recommendation.<sup>6</sup>

**sec-C<sub>4</sub>H<sub>9</sub>OH, 2-butanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants, over the temperature range 298–372 K.<sup>5</sup> A two-parameter fit up to 298 K gives A = -22.60 and B = 7095. Extrapolated values are in very good agreement with the results of Snider and Dawson<sup>8</sup> at 273 and 298 K and room temperature data from Butler et al.<sup>3</sup>

**tert-C<sub>4</sub>H<sub>9</sub>OH, 2-methyl-2-propanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants, over the temperature range 298–372 K.<sup>5</sup> Extrapolated values are in very good agreement with the results of Snider and Dawson<sup>8</sup> at 273 and 298 K and room temperature data from Butler et al.<sup>3</sup> The two data points of Snider and Dawson yield A = -23.63 and B = 8310.

#### Note 9: *Diols*

[Back to Table](#)

**Alkyl diols** The vapor pressure of the pure liquid and the activity coefficient of the dilute solution were determined from an analysis of literature data. These were then used to obtain the Henry's law values.<sup>1</sup>

- (1) Compernolle, S.; Müller, J. F. Henry's law constants of polyols. *Atmos. Chem. Phys.* **2014**, *14*, 12815-12837, doi:10.5194/acpd-14-13529-2014.

#### Note 10: *Polyols*

[Back to Table](#)

##### **HOCH<sub>2</sub>CH(OH)CH<sub>2</sub>OH, glycerol**

The vapor pressure of the pure liquid and the activity coefficient of the dilute solution were determined from an analysis of literature data. These were then used to obtain the Henry's law value.<sup>1</sup>

##### **HOCH<sub>2</sub>(CH(OH))<sub>2</sub>CH<sub>2</sub>OH, erythritol**

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyol.<sup>1</sup>

##### **C<sub>5</sub>H<sub>8</sub>(OH)<sub>4</sub>, pentaerythritol**

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyol.<sup>1</sup>

##### **C<sub>5</sub>H<sub>7</sub>(OH)<sub>5</sub>, xylitol, adonitol, arabitol**

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyols stereoisomers.<sup>1</sup> These values, xylitol ( $4.0 \times 10^{13}$ ), adonitol ( $4.7 \times 10^{13}$ ), and arabitol ( $6.8 \times 10^{13}$ ) were averaged to get the value in the Table.

##### **C<sub>6</sub>H<sub>8</sub>(OH)<sub>6</sub>, sorbitol, mannitol, glactitol**

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyols stereoisomers.<sup>1</sup> These values, sorbitol ( $6.7 \times 10^{16}$ ), mannitol ( $1.8 \times 10^{17}$ ), and glactitol ( $9.1 \times 10^{16}$ ) were averaged to get the value in the Table.

**Note 13: Aldehydes**[Back to Table](#)**HCHO**

The recommended value is the apparent Henry's law constant and includes a contribution due to hydrolysis  $H^* = H(1 + K_{hyd})$ . Data from Betterton and Hoffmann<sup>3</sup> and Zhou and Mopper<sup>9</sup> are in substantial agreement and were fit to a two-parameter expression. The more recent results of Allou et al.<sup>1</sup> are in complete agreement. Betterton and Hoffmann have calculated  $H = 2.5$  M atm<sup>-1</sup> at 298 K for the physical solubility. A gas-stripping study over the temperature range 5–50 °C agreed at room temperature, but was lower below and higher above room temperature.<sup>7</sup> Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured  $H$ .<sup>9</sup> For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M. Additional studies of the effect of NaCl as a function of temperature have been carried out by Allou et al.<sup>1</sup>

**CH<sub>3</sub>CHO**

The recommended value is the apparent Henry's law constant and includes a contribution due to hydrolysis  $H^* = H(1 + K_{hyd})$ . The results of Snider and Dawson,<sup>8</sup> Benkelberg et al.,<sup>2</sup> and Betterton and Hoffmann<sup>3</sup> are in excellent agreement and have been fit to a two-parameter expression for the recommendation. The results of Zhou and Mopper<sup>9</sup> curve off at higher temperatures and were not included in the fit. (Note the similar situation for acetone.) Betterton and Hoffmann<sup>3</sup> have calculated  $H = 4.8$  M atm<sup>-1</sup> at 298 K for the physical solubility. Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on

the measured  $H$ .<sup>9</sup> For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

**C<sub>2</sub>H<sub>5</sub>CHO** Results of Zhou and Mopper<sup>9</sup> and Snider and Dawson<sup>8</sup> agree only to within about a factor of two. The two points from the former were weighted by 3 and combined with the five points of the latter to generate the recommendation. A room temperature value of 9.26 M atm<sup>-1</sup> from a thermal desorption-GC/MS study is in good agreement with this recommendation.<sup>6</sup> Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured  $H$ .<sup>9</sup> For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

**C<sub>3</sub>H<sub>7</sub>CHO** The results from Zhou and Mopper<sup>9</sup> were fit to a two-parameter expression. A room temperature value of 6.19 M atm<sup>-1</sup> from a thermal desorption-GC/MS study is about 40% lower than this recommendation.<sup>6</sup> Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured  $H$ .<sup>9</sup> For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

#### **CHOCHO, glyoxal**

Measured using a bubble-column method.<sup>4</sup> Validation measurements on formaldehyde and acetic acid gave results of  $4.8 \times 10^3$  and  $5.0 \times 10^3$ , slightly higher than the recommendations here. The recommended value is the apparent Henry's law constant and includes a contribution due to hydrolysis  $H^* = H(1 + K_{hyd})$ . An intrinsic  $K_h = 1.90$  M atm<sup>-1</sup> was calculated at 298 K. The solubility increased by about a factor of three at 0.05 M NaCl, but dropped by ~50% when the concentration was increased to 5 M. Na<sub>2</sub>SO<sub>3</sub> concentrations of 0.0003 M to 0.03 M increased the solubility, up to a factor of ~50. Even higher sulfate concentrations led to values too high to measure. An earlier study reported only limiting values of  $\geq 3 \times 10^5$ .<sup>3</sup>

#### **HOCH<sub>2</sub>CHO, hydroxyacetraldehyde**

Apparent Henry's law measurements by a bubble-column technique at 25 and 45°C.<sup>3</sup> An intrinsic Henry's law constant of  $4.1 \times 10^3$  M atm<sup>-1</sup> at 298 K was calculated.

#### **CH<sub>3</sub>C(O)CHO, methyl glyoxal**

Apparent Henry's Law constant measured by a bubble-column technique.<sup>3</sup> An intrinsic Henry's law constant of 1.4 M atm<sup>-1</sup> at 298 K was calculated.

#### **CH<sub>2</sub>C(CH<sub>3</sub>)CHO, methacrolein**

Measured using a static technique with daily instrument calibrations and absolute determinations of partial pressures.<sup>5</sup> An uncertainty of  $\pm 0.7$  M atm<sup>-1</sup> was reported.

**Note 14: Ketones**

[Back to Table](#)

The recommendation is from a fit to the data of Snider and Dawson,<sup>10</sup> Benkelberg et al.,<sup>1</sup> Betterton,<sup>2</sup> and Strekowski and George.<sup>11</sup> Room temperature data points of Nozière and Riemer,<sup>8</sup> Hoff et al.,<sup>5</sup> Burnett,<sup>3</sup> and Vitenberg et al.<sup>12</sup> are in very good agreement. Results of Zhou and Mopper<sup>13</sup> are somewhat higher, particularly at room temperature and above. The situation is similar for acetaldehyde. Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured  $H$ .<sup>13</sup> For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M. The  $K_S$  values from this work are somewhat different than those obtained by Benkelberg et al.,<sup>1</sup> 0.089 vs 0.17 at 298 K and 0.17 vs 0.085 at 273 K. The magnitude of this difference is not too great, but the two studies predict a different sign for  $h_T$ .

The recommendation is from the two points of Snider and Dawson.<sup>10</sup> The room temperature points of Vitenberg et al.<sup>12</sup> and Rohrschneider<sup>9</sup> are in good agreement, while a room temperature value of 10.5 M atm<sup>-1</sup> from a thermal desorption-GC/MS study<sup>7</sup> is about 80% lower. The higher temperature data of Zhou and Mopper<sup>13</sup> are somewhat higher and those of Friant and Suffet<sup>4</sup> are lower than the recommendation. Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured  $H$ .<sup>13</sup> For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

Measured by a bubble-column technique.<sup>2</sup>

Measured using a static technique with daily instrument calibrations and absolute determinations of partial pressures.<sup>6</sup> An uncertainty of  $\pm 7$  M atm<sup>-1</sup> was reported.

**Note 15: C1 and C2 Organic Acids**

[Back to Table](#)

**HC(O)OH** The results of Johnson et al.<sup>3</sup> are accepted. The 298 K result of Khan et al.<sup>4</sup> is about 75% lower.

**CH<sub>3</sub>C(O)OH**

The results of Johnson et al.<sup>3</sup> are accepted. A value calculated from the NBS Thermodynamic tables<sup>6</sup> is about a factor of two higher.

**HC(OH)C(O)OH, glycolic acid**

Measured using a bubble-column method with no pH control (measured ~3–3.1).<sup>2</sup> Validation measurements on formaldehyde and acetic acid gave results of  $4.8 \times 10^3$  and  $5.0 \times 10^3$ , slightly higher than the recommendations in the Table. An intrinsic  $K_h = 2.37 \times 10^4 \text{ M atm}^{-1}$  was calculated at 298 K.

**HC(O)C(O)OH, glyoxylic acid**

Measured using a bubble-column method with no pH control (measured ~2.6–2.8).<sup>2</sup> Validation measurements on formaldehyde and acetic acid gave results of  $4.8 \times 10^3$  and  $5.0 \times 10^3$ , slightly higher than the recommendations in the Table. An intrinsic  $K_h = 28.67 \text{ M atm}^{-1}$  was calculated at 298 K.

**CH<sub>3</sub>C(O)C(O)OH, pyruvic acid**

Taken from Khan et al.<sup>4</sup> Salt effect derived from effect of NaCl ( $k_s = 0.236 \text{ M}^{-1}$ ) and KCl ( $k_s = 0.235 \text{ M}^{-1}$ ) on the partial pressure over 1.5 M solution of pyruvic acid at various salt concentrations. Much different values derived when other salts were used, suggesting complications due to specific interactions and, possibly, to the weakly buffered nature of the solution.

**HOC(O)C(O)OH, oxalic acid**

Determined from the solubility, water activity, obtained by a review of the literature, and solution vapor pressure of the acid.<sup>1</sup> The first two were obtained by a review of the literature; the vapor pressure was from evaporation measurements on levitated particles.<sup>5</sup>

**Note 16: C<sub>3</sub> and Higher Organic Acids**

[Back to Table](#)

**HOC(O)CH<sub>2</sub>C(O)OH, malonic acid**

The solubility and water activity for the acid were obtained through a review of the literature. These were combined with solid vapor pressure<sup>1</sup> or solution vapor pressure<sup>4</sup> data to derive Henry's law values of  $0.94 \times 10^{10}$  and  $3.9 \times 10^{10}$  M atm<sup>-1</sup>.<sup>2</sup>

**HOC(O)CH<sub>2</sub>CH<sub>2</sub>C(O)OH, succinic acid**

The solubility and water activity for the acid were obtained through a review of the literature. These were combined with solid vapor pressure<sup>1</sup> or solution vapor pressure<sup>4</sup> data to derive Henry's law values of  $2.0 \times 10^9$  and  $4.2 \times 10^9$  M atm<sup>-1</sup>.<sup>2</sup>

**HOC(O)(CHOH)<sub>2</sub>C(O)OH, tartaric acid**

Determined from the solubility, water activity, obtained by a review of the literature, and liquid vapor pressure of the acid.<sup>2</sup> The first two were obtained by a review of the literature; the vapor pressure was obtained from the evaporation rate of levitated, supersaturated liquid particles.<sup>3</sup> The value listed is the midpoint of the range ( $0.7\text{--}9.3 \times 10^{17}$ ) from the uncertainty in the vapor pressure data.

**HOC(O)C<sub>3</sub>H<sub>6</sub>C(O)OH, glutaric acid**

The solubility and water activity for the acid were obtained through a review of the literature. These were combined with solid vapor pressure<sup>1</sup> or solution vapor pressure<sup>4</sup> data to derive Henry's law values of  $2.4 \times 10^9$  and  $5.2 \times 10^9$  M atm<sup>-1</sup>.<sup>2</sup>

**HOC(O)C<sub>4</sub>H<sub>8</sub>C(O)OH, adipic acid**

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the acid.<sup>2</sup> The first two were obtained by a review of the literature; the vapor pressure was from evaporation rates of aerosol samples.<sup>1</sup>

**(CH<sub>2</sub>C(O)OH)<sub>2</sub>C(OH)C(O)OH, citric acid**

Determined from the solubility, water activity, obtained by a review of the literature, and liquid vapor pressure of the acid.<sup>2</sup> The first two were obtained by a review of the literature; the vapor pressure was obtained from the evaporation rate of levitated, supersaturated liquid particles.<sup>3</sup> The value listed is the midpoint of the range ( $0.2\text{--}6 \times 10^{17}$ ) from the uncertainty in the vapor pressure data.

**Note 23: Nitro compounds**

[Back to Table](#)

**Nitroalkanes (CH<sub>3</sub>NO<sub>2</sub>, C<sub>2</sub>H<sub>5</sub>NO<sub>2</sub>, C<sub>3</sub>H<sub>7</sub>NO<sub>2</sub>, and CH<sub>3</sub>CH(NO<sub>2</sub>)CH<sub>3</sub>)**

The recommended values are all taken from the work of Benes and Dohnal.<sup>1</sup> For nitromethane, the 298 K value from Rohrschneider<sup>9</sup> is about 30% higher.

**Alkyl nitrates (CH<sub>3</sub>ONO<sub>2</sub>, C<sub>2</sub>H<sub>5</sub>ONO<sub>2</sub>, 1-C<sub>3</sub>H<sub>7</sub>ONO<sub>2</sub>, 2-C<sub>3</sub>H<sub>7</sub>ONO<sub>2</sub>, 1-C<sub>4</sub>H<sub>9</sub>ONO<sub>2</sub>, 2-C<sub>4</sub>H<sub>9</sub>ONO<sub>2</sub>)**

The recommended values are all taken from the work of Kames and Schurath.<sup>7</sup> The results of Luke et al.<sup>8</sup> are in very good agreement for 1-butyl and 2- butyl nitrates, but the values reported by Hauff<sup>4</sup> for 1- and 2-propyl and butyl nitrates by head-space chromatography are significantly (~50%) lower.

**CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub> (PAN)**

The results of Kames and Schurath<sup>7</sup> and Frenzel et al.<sup>3</sup> are close and were used for the recommendation. They are somewhat higher (~60%) than the single temperature point of Holdren et al.<sup>5</sup> Kames and Schurath<sup>7</sup> and Holdren et al.<sup>5</sup> also measured hydrolysis rate constants. K<sub>s</sub> = 0.0807 M<sup>-1</sup> for NaCl at 293.2 K based on solubility in artificial sea water (~0.7 M).<sup>7</sup>

**Bifunctional alkyl nitrates**

The recommended values (at 293 K) are taken from the work of Kames and Schurath.<sup>6</sup>

 **$\text{CH}_3\text{CH}(\text{ONO}_2)\text{CH}_2\text{ONO}_2$ , 1,2-propane dinitrate**

Direct measurement at 293 K.<sup>6</sup> A much lower value of  $33 \text{ atm}^{-1} \text{ L}^{-1}$  mol was calculated from vapor pressure and solubility measurements.<sup>2</sup>

 **$\text{O}_2\text{NO}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{ONO}_2$ , 1,3-propane dinitrate**

Calculated from vapor pressure and solubility measurements.<sup>2</sup> Note that the value for 1,2-propane dinitrate was much lower than that directly measured.

 **$\text{CCl}_3\text{NO}_2$ , chloromethyl nitrate (chloropicrin)**

Measured by a stripping technique in water, 0.1 M and 0.2 M NaCl, and at pH 4.0 and 8.0 (buffered). All values were within the stated margin of error ( $\pm 0.3$ ).<sup>10</sup>

[Back to Table](#)

**CCl<sub>3</sub>CHO** 1,1,1-trichloroacetaldehyde (chloral). Apparent Henry's law constant measured by head-space analysis.<sup>1</sup> An intrinsic Henry's law constant of 14 mol L<sup>-1</sup> atm<sup>-1</sup> at 25°C was derived. Listed parameters from a refit to the data.

- (1) Betterton, E. A.; Hoffmann, M. R. Henry's law constants of some environmentally important aldehydes. *Environ. Sci. Technol.* **1988**, *22*, 1415-1418.

**Note 27:** *Haloacids*

[Back to Table](#)

**CFH<sub>2</sub>C(O)OH**

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 mol kg<sup>-1</sup> HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.<sup>1</sup> Due to high toxicity, only a single determination was made for this acid.

**CF<sub>2</sub>HC(O)OH**

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg<sup>-1</sup> HBr to suppress dissociation.<sup>1</sup> Reported values corrected for the effect on the activity of the solution.

**CF<sub>3</sub>C(O)OH, trifluoroacetic acid**

Values derived at 178, 288, and 298 K from the simultaneous measurement of the equilibrium partial pressures of TFA over aqueous solutions and the concentration of undissociated TFA in solution using total reflection IR spectroscopy.<sup>2</sup> The previous recommended value from the equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing HBr to suppress dissociation, assuming a pK<sub>a</sub> value of 0.47 at 298 K.<sup>1</sup> The results of Kutsuna and Hori suggest a pK<sub>a</sub> value of 0.2. It has been pointed out that there are large discrepancies in reported pK<sub>a</sub> values for TFA, which are not fully understood.<sup>3</sup>

**CClH<sub>2</sub>C(O)OH and CCl<sub>2</sub>HC(O)OH**

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg<sup>-1</sup> HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.<sup>1</sup>

**CCl<sub>3</sub>C(O)OH**

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.25 to 6.0 mol kg<sup>-1</sup> HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.<sup>1</sup>

**CCIF<sub>2</sub>C(O)OH and CBrF<sub>2</sub>C(O)OH**

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg<sup>-1</sup> HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.<sup>1</sup>

**CBr<sub>3</sub>C(O)OH**

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg<sup>-1</sup> HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.<sup>1</sup> Only a few measurements at 308 K and one at 298 K were made. The reported value of B is the mean of those for CF<sub>3</sub>C(O)OOH and CCl<sub>3</sub>C(O)OOH.<sup>1</sup>

**Note 29: Halogens**

[Back to Table](#)

**Cl**

From the reduction potential  $E^\circ(\text{Cl}/\text{Cl}^-) = (2.43 \pm 0.03) \text{ V}$ , together with the Gibbs energy for the anion and the gas-phase atom. The potential was derived from an analysis of the reaction of OH with Cl<sup>-</sup>, yielding the equilibrium constant for  $\text{OH} + \text{Cl}^- + \text{H}^+ \leftrightarrow \text{H}_2\text{O} + \text{Cl}$  ( $K_{\text{eq}} = 1.1 \times 10^5 \text{ M}^{-2}$ , corrected to a standard state of water at unit activity),<sup>8</sup> and the reduction potential  $E^\circ(\text{OH}^-, \text{H}^+/\text{H}_2\text{O}) = (2.73 \pm 0.02) \text{ V}$ .<sup>7</sup>

**Cl<sub>2</sub>**

Three-parameter refit to the recommendation of Battino.<sup>3</sup> Two parameter fit gives A = 9.38 and B = 2090 K for the temperature range 283–313 K. A more recent study in which the chlorine solubility was determined by measuring the total molecular chlorine concentration in contact with pure chlorine gas resulted in values of 0.11 mol L<sup>-1</sup> atm<sup>-1</sup> at 10°C, 0.074 at 20°C, and 0.052 at 30°C.<sup>1</sup>

<b>Br<sub>2</sub></b>	The results of Kelley and Tartar <sup>6</sup> and Jenkins and King <sup>5</sup> agree well below about 313 K, and with the 298 K point of Hill et al. <sup>4</sup> Recommendation based on a two-parameter fit to all data at and below 308 K.
<b>BrCl</b>	The recommendation is from the work of Barlett and Margerum. <sup>2</sup>

**Note 30: Inorganic Halogen Species**

[Back to Table](#)

<b>ClO</b>	From the reduction potential $E(\text{ClO}/\text{ClO}^-) = (1.41 \pm 0.02)\text{V}$ , which is based on an equilibrium with carbonate at high pH and ionic strength. <sup>5</sup> This was combined with the Gibbs energy of the anion and the gas-phase radical to obtain the free energy of solution. Due to the high ionic strength, 3 M, it was not possible to correct the potential value and obtain a reduction potential for the standard state. Thus, the derived Henry's law constant must be considered uncertain.
<b>Cl<sub>2</sub>O</b>	Fit to recommendation of Wilhelm et al. <sup>7</sup> Data appear somewhat uncertain.
<b>ClO<sub>2</sub></b>	Two-parameter fit to the recommendation of Battino. <sup>1</sup>
<b>HOCl</b>	Huthwelker et al. <sup>6</sup> analyzed the limited data for pure water from Blatchley et al., <sup>2</sup> Holzwarth et al., <sup>4</sup> and the more extensive data for uptake by sulfuric acid from Hanson and Ravishankara, <sup>3</sup> along with thermodynamic information, and obtained a consistent expression for the solubility of HOCl.
<b>HOBr</b>	The Henry's law constant was estimated to be more than twice that of HOCl based on a study of the effective Henry's law constant for free bromine from a stripping column. <sup>2</sup>

[Back to Table](#)

<b>SO<sub>2</sub></b>	The recommendation of Battino <sup>1</sup> was accepted and refit to a three-parameter equation. The earlier recommendation of Edwards et al. <sup>3</sup> is slightly lower. A two parameter fit gives A = -9.53 and B = 2930 K for the temperature range 278–298 K. New value of h <sub>SO<sub>2</sub>,0</sub> from absorption equilibria studies in aqueous HCl and NaCl solutions. <sup>8</sup> Temperature dependence, h <sub>T</sub> , from the optimization of Weisberger and Schumpe. <sup>10</sup>
<b>H<sub>2</sub>S</b>	In the recommendation of Fogg, <sup>5</sup> two expressions were given, representing the results above and below 283 K. The predicted values from these expressions were calculated, with the points at 283 K averaged, converted to the desired units, and then fit with the two- and three-parameter expressions. These are the recommended values. More recent results of Rinker and Sandall <sup>7</sup> and Munder et al. <sup>6</sup> are slightly lower; in these studies, the physical solubility of H <sub>2</sub> S was determined through measurements involving aqueous solutions of glycols or amines, neutralized with HCl. The reported values of De Bruyn et al. <sup>2</sup> are significantly (~30%) lower. The earlier recommendation of Edwards et al. <sup>3</sup> is very close to the recommendation of Fogg <sup>5</sup> as is the recommendation of Yaws et al. <sup>12</sup> The room temperature point calculated from the NBS Thermodynamic tables Wagman et al. <sup>9</sup> is also slightly lower. The work of De Bruyn et al. <sup>2</sup> covered also a wide range of NaCl and (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> concentration and of pH. Salt effect parameters taken from the optimization of Weisberger and Schumpe. <sup>10</sup>
<b>CS<sub>2</sub></b>	The recommendation is from a fit to data of Elliott, <sup>4</sup> who also present data in 0.5 mol L <sup>-1</sup> NaCl. The results of De Bruyn et al. <sup>2</sup> are significantly (50%) lower. The work of De Bruyn et al. <sup>2</sup> covered also a wide range of NaCl and (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> concentration and of pH. Salt effect parameters derived from the ratio of the solubility of CS <sub>2</sub> in water and 0.5 M NaCl. <sup>1</sup> At 278 K, k <sub>s</sub> = 0.184 M <sup>-1</sup> , compared to 0.150 M <sup>-1</sup> from the results of De Bruyn, et al. Note also De Bruyn, et al. <sup>2</sup> obtained K <sub>s</sub> = 0.410 M <sup>-1</sup> for (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> , whereas these parameters would predict 0.261 M <sup>-1</sup> .
<b>COS</b>	The reviews by Wilhelm et al. <sup>11</sup> and Yaws et al <sup>12</sup> result in identical values over the low temperature range (<303 K) and are combined to generate the recommendation. The results of De Bruyn et al <sup>2</sup> are somewhat (~25%) lower at the lower temperature range. The work of De Bruyn et al <sup>2</sup> covered also a wide range of NaCl and (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> concentration and of pH.

[Back to Table](#)

<b>CH<sub>3</sub>SH</b>	The recommendation is based on the data of Przyjazny et al. <sup>4</sup> Results of De Bruyn et al. <sup>3</sup> are about half the recommended value at 298 K. The work of De Bruyn et al. <sup>3</sup> covered a wide range of pH and NaCl and (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> concentrations. At 298 K, they obtained K <sub>s</sub> = 0.314 M <sup>-1</sup> for (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> and K <sub>s</sub> = 0.143 M <sup>-1</sup> for NaCl. From the latter, we calculate h <sub>G</sub> = 0.003 M <sup>-1</sup> ; the values for (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> from this work have tended to be high.
<b>C<sub>2</sub>H<sub>5</sub>SH</b>	The recommendation is based on the data of Przyjazny et al. <sup>4</sup> The results of Vitenberg <sup>6</sup> are slightly lower than the extrapolated value at 293 K.
<b>CH<sub>3</sub>SCH<sub>3</sub></b>	The recommendation is based on the values of Dacey et al. <sup>2</sup> The single temperature point of Wong and Wang <sup>8</sup> and the higher temperature results of Przyjazny et al. <sup>4</sup> are in good agreement. The results of De Bruyn et al. <sup>3</sup> are about 30% lower. A more recent value of 0.47 M atm <sup>-1</sup> at 298 K, in good agreement with the value recommended here, was obtained by a dynamic gas stripping approach coupled to a mass spectrometer. <sup>5</sup> The studies of Dacey et al. <sup>2</sup> and Wong and Wang <sup>8</sup> were also carried out with seawater. The work of De Bruyn et al. <sup>3</sup> covered also a wide range of NaCl and (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> concentration and of pH. Salt effect parameters based on the values of Dacey et al. <sup>2</sup> for Sargasso sea water from 0 to 29 C. The values for K <sub>H</sub> obtained by Wong and Wang <sup>8</sup> for sea water from 18 to 44 C are in good agreement. Dacey et al. <sup>2</sup> also measured K <sub>H</sub> at 18 C for NaCl solutions up to 32%. For the 10–32% data, a value of K <sub>s</sub> = 0.117 M <sup>-1</sup> can be derived, in good agreement with the predicted value of 0.113 M <sup>-1</sup> . The 278 K value of K <sub>s</sub> = 0.180 M <sup>-1</sup> obtained by De Bruyn et al. <sup>3</sup> is somewhat larger. Note also the De Bruyn, et al. <sup>3</sup> obtained K <sub>s</sub> = 0.332 M <sup>-1</sup> for (NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub> , whereas these values would predict 0.223.
<b>CH<sub>3</sub>SC<sub>2</sub>H<sub>5</sub>, C<sub>2</sub>H<sub>5</sub>SC<sub>2</sub>H<sub>5</sub>, CH<sub>2</sub>CHCH<sub>2</sub>SCH<sub>3</sub>, higher alkyl sulfides</b>	Obtained by a dynamic gas stripping approach coupled to a mass spectrometer. <sup>5</sup> An uncertainty of $\pm 0.03$ M atm <sup>-1</sup> was estimated for CH <sub>3</sub> SC <sub>2</sub> H <sub>5</sub> , of $\pm 0.01$ M atm <sup>-1</sup> for C <sub>2</sub> H <sub>5</sub> SC <sub>2</sub> H <sub>5</sub> , and $\pm 0.02$ M atm <sup>-1</sup> for CH <sub>2</sub> CHCH <sub>2</sub> SCH <sub>3</sub> .
<b>CH<sub>3</sub>S(O)CH<sub>3</sub></b>	The recommendation is from Watts and Brimblecombe <sup>7</sup> cited by Allen et al. <sup>1</sup>
<b>CH<sub>3</sub>NCS, methyl isothiocyanate</b>	Measured by stripping technique in pure water. <sup>9</sup> Measurements in NaCl and buffer solutions tended to be lower (0.1 M NaCl, 9 M atm <sup>-1</sup> ; 0.2 M, 7 M atm <sup>-1</sup> ).
<b>CH<sub>3</sub>SSCH<sub>3</sub> and C<sub>2</sub>H<sub>5</sub>SSC<sub>2</sub>H<sub>5</sub></b>	Obtained by a dynamic gas stripping approach coupled to a mass spectrometer. <sup>5</sup> An uncertainty of $\pm 0.04$ M atm <sup>-1</sup> was estimated for CH <sub>3</sub> SSCH <sub>3</sub> and $\pm 0.03$ M atm <sup>-1</sup> for C <sub>2</sub> H <sub>5</sub> SSC <sub>2</sub> H <sub>5</sub> .

The values in this table can be used to estimate the solubility of a gas in various mixed electrolyte solutions, even if these data have not been obtained experimentally for all of the ions. For example, the solubility of ozone in a solution of 0.8 M HCl and 1.2 M Na<sub>2</sub>SO<sub>4</sub> at 273 K would be estimated as follows:

First,  $H^o = 0.024 \text{ M atm}^{-1}$  at 273 K, from the Henry's Law Table; from the same Table, the gas-specific parameters for ozone are  $h_{G,o} = 0.00396 \text{ M}^{-1}$  and  $h_T = 1.79 \times 10^{-3} \text{ M}^{-1} \text{ K}^{-1}$ , thus:

$$k_G = 0.00396 + 1.79 \times 10^{-3} \times (273 - 298) = -0.0408 \text{ M}^{-1}$$

The specific ion parameters from Table 5-4 are corrected by this value to calculate the change in the logarithm of the Henry's law constant

$$\begin{aligned} \log(H^o/H^{273}) &= 2 \times 1.2 \text{ M} \times (0.1143 - 0.0408) \text{ M}^{-1} + 1.2 \text{ M} \times (0.1117 - 0.0408) \text{ M}^{-1} + \\ &0.8 \text{ M} \times (0 - 0.0408) \text{ M}^{-1} + 0.8 \text{ M} \times (0.0318 - 0.0408) \text{ M}^{-1} = 0.181 \end{aligned}$$

$$\text{Thus, } (H^o/H^{273}) = 1.517$$

$$H = 0.024 \text{ M atm}^{-1}/1.517 = 0.016 \text{ M atm}^{-1} \text{ for O}_3 \text{ in this salt solution at 273 K.}$$

## 5.20 Notes to Table 5-6

1. **O<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Bubble train uptake measurements were performed by Rattigan et al.<sup>1</sup> at 293 K for 1–70 wt% H<sub>2</sub>SO<sub>4</sub>. Recommended expression is a Sechenov coefficient formulation where H<sub>o</sub> = 0.012 M atm<sup>-1</sup> is the 293 K value of H for pure water from Wilhelm et al.<sup>2</sup> In the measurement, account was taken of the loss of O<sub>3</sub> due to reaction with H<sup>+</sup>.

- (2) Wilhelm, E.; Battino, R.; Wilcock, R. J. Low-pressure solubility of gases in liquid water. *Chem. Rev.* **1977**, *77*, 219–262.

2. **NO<sub>2</sub> in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Langenberg et al.<sup>1</sup> present novel capillary gas chromatography measurements for 39, 59, and 68 wt% H<sub>2</sub>SO<sub>4</sub> over the temperature range of 203 to 243 K. However, NO<sub>2</sub> solubility must be derived from chromatographic waveforms, which are contorted by much higher N<sub>2</sub>O<sub>4</sub> solubility. The resulting values for H<sub>NO<sub>2</sub></sub> are in the 1 to 10<sup>2</sup> range, but show inconsistent trends with temperature and concentration, indicating possibly large systematic error.

3. **HONO in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Becker et al.<sup>1</sup> measured HONO partial pressure, P<sub>HONO</sub>, over bulk solutions in a temperature range of 248–298 K and a H<sub>2</sub>SO<sub>4</sub> concentration range of 0–67 wt%. Longfellow et al.<sup>2</sup> measured P<sub>HONO</sub> in a wetted wall flow reactor over a temperature range of 218–295 K and an acid concentration range of 60–83 wt%. Agreement between these two data sets is excellent. H\* decreases from 0 wt% to 53 wt% due to physical solubility, then increases above 53 wt% due to protonation and/or association with H<sub>2</sub>SO<sub>4</sub> to make nitrosyl sulfuric acid. Becker et al. parameterized their data as a function of sulfuric acid wt% and temperature. However, the Becker et al. parameterization is not able to fit the combined sets of Becker et al.<sup>1</sup> and Longfellow et al.<sup>2</sup> data, particularly at the lower temperatures and higher wt% most relevant to the stratosphere. Therefore, the recommended functional form was used to fit the data for >60 wt%. This function fits both sets of data very well. It is important to note that this function is only valid for H<sub>2</sub>SO<sub>4</sub> concentrations near 60 wt% and above. The parameterization in Becker et al.<sup>1</sup> should be used to calculate H for H<sub>2</sub>SO<sub>4</sub> concentrations <60 wt%. (Note that the units for H are mol/kg-bar in Becker et al.<sup>1</sup> The density parameterization of Myhre et al.<sup>3</sup> was used to convert to M/atm units.)

4. **HNO<sub>3</sub> and HCl in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l) and H<sub>2</sub>SO<sub>4</sub>•nHNO<sub>3</sub>•mH<sub>2</sub>O(l).** Effective Henry's law coefficients, H\*, for HNO<sub>3</sub>, and HCl in binary H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O and ternary H<sub>2</sub>SO<sub>4</sub>/HNO<sub>3</sub>/H<sub>2</sub>O solutions over the temperature range 195 to 300 K are required to model the composition and heterogeneous chemistry of stratospheric and upper tropospheric aerosols. Solubility data can be obtained from analysis of heterogeneous uptake experiments with the liquid phase diffusion coefficient estimated from acid solution viscosity (Williams and Long<sup>15</sup>). Solubilities can also be obtained from equilibrium or from vapor pressure data.

Experimental solubility data for HNO<sub>3</sub> is provided by Van Doren et al.,<sup>12</sup> Reihs et al.,<sup>9</sup> and Zhang et al.<sup>16</sup> Data for HCl solubility is provided by Watson et al.,<sup>13</sup> Hanson and Ravishankara,<sup>5,6</sup> Zhang et al.,<sup>16</sup> Williams and Golden,<sup>14</sup> Abbatt,<sup>1</sup> Elrod et al.,<sup>4</sup> and Robinson et al.<sup>10</sup>

These studies all show that trace species solubility in H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O and H<sub>2</sub>SO<sub>4</sub>/HNO<sub>3</sub>/H<sub>2</sub>O solutions is a strong function of water activity, which, in turn, depends on both temperature and acid concentrations. Prediction of

$\text{HNO}_3$  and  $\text{HCl}$   $\text{H}^*$  values for atmospheric compositions requires a sophisticated model. Comprehensive thermodynamic models of acid solutions for a range of atmospheric conditions have been published by Carslaw et al.,<sup>2</sup> Tabazadeh et al.,<sup>11</sup> and Luo et al.<sup>7</sup> and reviewed by Carslaw et al.<sup>3</sup> These models do an excellent job of reproducing the available experimental data, even for ternary  $\text{H}_2\text{SO}_4/\text{HNO}_3/\text{H}_2\text{O}$  solutions (Elrod et al.<sup>4</sup>). These models and the Carslaw et al.<sup>3</sup> review should be consulted for plots/predictions of  $\text{H}^*$  for  $\text{HNO}_3$  and  $\text{HCl}$  in strong acid solutions over the atmospheric temperature range. The most widely used model of Carslaw et al.<sup>2</sup> was revised in Massucci et al.<sup>8</sup>

5.  **$\text{HO}_2\text{NO}_2$  in  $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}(\text{l})$ .** Zhang et al.<sup>3</sup> performed wetted wall flow reactor studies using CIMS to detect  $\text{HO}_2\text{NO}_2$  uptake over a temperature range of 201–230 K and an acid concentration range of 52.9–74 wt%  $\text{H}_2\text{SO}_4$ .  $\text{HD}_1^{1/2}$  values were determined for 52.9, 58.3/59.1, 66.4 and 73.8/74 wt%, with 5 to 15 data points per temperature or temperature pair. All uptake appeared to be reversible with the variation in  $\text{H}$  strongly temperature dependent, but only moderately dependent on  $\text{H}_2\text{SO}_4$  wt%.  $\text{D}_1$  values were calculated from a cubic cell model to derive  $\text{H}$ . Uncertainties in measured  $\text{H}$  values were estimated by authors to be 25% for  $\text{H} < 1 \times 10^6 \text{ M atm}^{-1}$  and 50% for  $\text{H} > 1 \times 10^6 \text{ M atm}^{-1}$ . These data were parameterized by Leu and Zhang<sup>2</sup> in the Sechenov coefficient form adopted by Huthwelker et al.<sup>1</sup> for  $\text{HOCl}$ , and their formulation is recommended.

- (3) Zhang, R.; Leu, M.-T.; Keyser, L. F. Heterogeneous chemistry of HO<sub>2</sub>NO<sub>2</sub> in liquid sulfuric acid. *J. Phys. Chem. A* **1997**, *101*, 3324-3330.

**6. CH<sub>2</sub>O in H<sub>2</sub>SO<sub>4</sub>•mHNO<sub>3</sub>•nH<sub>2</sub>O(l).** The recommended Henry's Law relationship is:

$$H^* = H(1 + K_2 a_{H_2O} + K_3 a_{H^+})$$

where:  $H = 3.4 \times 10^{-5} \exp -[(-0.0456 + 55.5/T)(0.46 m_{H_2SO_4} + 0.13 m_{HNO_3})]$  M atm<sup>-1</sup>, T is the temperature in K, and  $m_{H_2SO_4}$  and  $m_{HNO_3}$  are the respective acid molalities;  $K_2 = \exp(4020/T - 5.83)$  M<sup>-1</sup>,  $K_3 = 0.56 \exp [8.84 - (T - 260/T)]$  M<sup>-1</sup>, and  $a_{H_2O}$  and  $a_{H^+}$  are the water and H<sup>+</sup> activities which are obtained from a thermodynamic model of the solution, e.g. Carslaw et al.<sup>1</sup> Valid for 10–85 wt% H<sub>2</sub>SO<sub>4</sub>, 8–40 wt% HNO<sub>3</sub>, T = 240–300 K.

Knudsen cell studies by Tolbert et al.<sup>4</sup> and Iraci and Tolbert<sup>2</sup> and droplet train/reactor studies by Jayne et al.<sup>3</sup> all yield data showing that CH<sub>2</sub>O is strongly absorbed by sulfuric acid solutions, and Jayne et al. also provide data for ternary acid solutions. The Jayne et al.<sup>3</sup> study included H<sub>2</sub>SO<sub>4</sub> concentrations from 10 to 85 wt% and HNO<sub>3</sub> concentration between 8 and 40 wt% with temperature variations from 241 to 300 K. These data were parameterized with three terms, representing physical CH<sub>2</sub>O solubility, reversible hydrolysis to CH<sub>2</sub>(OH)<sub>2</sub>, important in more dilute solutions, and reversible formation of CH<sub>3</sub>O<sup>+</sup>, dominant at high acidities. The Jayne et al.<sup>3</sup> parameterization is recommended above. The H<sup>\*</sup> data from Iraci and Tolbert<sup>2</sup> cover 49 to 95 wt% H<sub>2</sub>SO<sub>4</sub> and a temperature range of 197 to 214.5 K and are in fair agreement with extrapolation of H<sup>\*</sup> expression from Jayne et al.<sup>3</sup> for concentrations below ~75 wt%. However, the Iraci and Tolbert data are taken on such thin acid films that initial uptake slopes are difficult to determine accurately and the data scatter is large. While the Iraci and Tolbert data do indicate significantly larger H<sup>\*</sup> values for H<sub>2</sub>SO<sub>4</sub> concentrations above 75 wt%, the data do not compel a reformulation of the Jayne et al. parameterization.

**7. CH<sub>3</sub>OH in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** H<sup>\*</sup> data from Kane and Leu,<sup>3</sup> taken over 40–85 wt% H<sub>2</sub>SO<sub>4</sub> and from 210–235 K, indicate soluble uptake below 65 wt% and predominately reactive uptake to form methanesulfonic acid and dimethylsulfate above 65 wt%. Uptake decreased slightly with temperature below 65 wt% and increases slightly with temperature above. Data yield H<sup>\*</sup>k<sup>1/2</sup> at high acid concentrations. Weakly temperature dependent  $\gamma_S$  of ~0.15 were measured for 65, 75, and 80 wt%. However, Knudsen cell studies by Iraci et al.<sup>1</sup> at 45, 61 and 72 wt% over a 197–223 K temperature range show only well behaved reversible uptake. They argue that low vapor pressures explain the lack of CH<sub>3</sub>OH recovery for the short observation times used by Kane and Leu. They also cite three older literature studies on the reaction of methanol and ethanol at room temperature in sulfuric acid which report reaction rate constants much lower than those deduced by Kane and Leu.<sup>1</sup> Iraci et al. present the following parameterization of their data plus data for water:

$$\log H^* = A + 1000B/T$$

where A = 7.00 + log M<sub>H2O</sub>, B = 0.000619 m<sup>2</sup> + 0.00544 m + 2.267, M<sub>H2O</sub> is the molarity of water in the solution (mol L<sup>-1</sup>) and m is the molality of the H<sub>2</sub>SO<sub>4</sub> (moles H<sub>2</sub>SO<sub>4</sub> per kg H<sub>2</sub>O).

Note that this parameterization is based only on the Iraci et al. data. A reanalysis of the Kane and Leu<sup>3</sup> results to provide additional data in the 40–72 wt% range, and H<sup>\*</sup> values for higher wt% should be undertaken to validate and extend the Iraci et al. data.

Iraci et al.<sup>2</sup> used infrared spectroscopy to monitor the production of gas phase methyl nitrate, CH<sub>3</sub>ONO<sub>2</sub>, from the bulk reaction of ternary sulfuric acid/nitric acid/water solutions with 0.00005–0.005 M CH<sub>3</sub>OH in 50.5 to 63.6 wt% H<sub>2</sub>SO<sub>4</sub> with 0.03–0.21 M HNO<sub>3</sub> between 278.2 and 328.6 K. This reaction may complicate determinations of Henry's law solubility of methanol in ternary acid solutions when sulfuric acid concentrations are high enough (probably >70 wt%) to produce high levels of NO<sub>2</sub><sup>+</sup>, the assumed nitrating agent.

- 8. CH<sub>3</sub>CH<sub>2</sub>OH in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O (l).** Michelsen et al.<sup>1</sup> reported Knudsen cell ethanol uptake experiments for 36–76 wt% H<sub>2</sub>SO<sub>4</sub> over a 209–237 K temperature range as well as equilibrium ethanol vapor pressure measurements for 0.5 M ethanol in 59.1 wt% acid between 214.3 and 230.8 K and 0.1 M ethanol in 38.5 wt% acid between 214.0 and 223.9 K. Henry's law solubility parameters from the two methods agreed well. Solubility increased dramatically with increasing acid wt% and decreasing temperature. Michelsen et al. present the following parameterization of their data:

$$\log H^* = A + 1000B/T$$

where A = ΔS°/2.303R + log M<sub>H2O</sub>, B = 5.319 (χ<sub>acid</sub>)<sup>2</sup> + 0.812 (χ<sub>acid</sub>) + 2.647, and ΔS° is -174 J mol<sup>-1</sup> K<sup>-1</sup>, M<sub>H2O</sub> is the molarity of water in the solution calculated at 220K (mol L<sup>-1</sup>) and χ<sub>acid</sub> is the mole fraction of sulfuric acid in the solution. Representative values of these parameters are presented in Table 2 of Michelsen et al.<sup>1</sup> Williams et al.<sup>3</sup> performed Knudsen cell H\* measurements on the effect of 0.1M acetone on the uptake of ethanol by 38.4 wt% H<sub>2</sub>SO<sub>4</sub> at 219.1 K yielding H\* = (2.2 ± 0.1) × 10<sup>5</sup> M atm<sup>-1</sup> in good agreement with values without added acetone reported by Michelsen et al.<sup>1</sup> and Timonen and Leu,<sup>2</sup> indicating no effect of added acetone.

Timonen and Leu<sup>2</sup> calculated H\* values from their uptake coefficients on 41.1 wt% H<sub>2</sub>SO<sub>4</sub> that are in moderate agreement with the Michelsen et al. parameterization.

- 9. CH<sub>3</sub>CHO in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Michelsen et al.<sup>1</sup> reported Knudsen cell acetaldehyde uptake experiments for 39–76 wt% H<sub>2</sub>SO<sub>4</sub> over a 211–241 K temperature range. Tabulated H\* values for 37 experiments covering four acid concentrations ranged from 2 × 10<sup>2</sup> to 1.5 × 10<sup>5</sup> M atm<sup>-1</sup>; with highest values at highest acid concentration and lowest temperatures. Data for the highest acid concentrations (~76 wt% H<sub>2</sub>SO<sub>4</sub>) generally indicated simple solubility behavior, while some measurements at lower acid concentrations (39–66 wt%) showed indications of reactive uptake.

Williams et al.<sup>2</sup> performed Knudsen cell H\* measurements on the effect of 0.1M ethanol or acetone on the uptake of acetaldehyde, reproducing a few temperatures and acid concentrations used for the data reported in Michelsen et al.<sup>1</sup> The solubility of acetaldehyde in acid with 0.1 M ethanol or 0.1 M acetone was nearly an order of magnitude higher than the corresponding organic free measurements. Two measurements at 216.1 and 226.8 K with 0.0016 M formaldehyde added to 38.5 wt% H<sub>2</sub>SO<sub>4</sub> showed no H\* enhancement over organic free measurements but time resolved uptake measurements showed evidence for enhanced reactive uptake.

- (2) Williams, M. B.; Michelsen, R. R. H.; Axson, J. L.; Iraci, L. T. Uptake of acetone, acetaldehyde and ethanol in cold sulfuric acid solutions containing organic material: Carbon accretion mechanisms. *Atmos. Environ.* **2010**, *44*, 1145-1151, doi:10.1016/j.atmosenv.2009.12.036.
- 10. CH<sub>3</sub>C(O)CH<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Duncan et al.<sup>2,3</sup> used IR spectra of thin sulfuric acid films to establish that acetone is absorbed as the protonated species. Above 70 wt% protonated acetone undergoes a self-condensation/dehydration reaction to form protonated mesityl oxide, which, in turn, reacts with an additional protonated acetone to form trimethyl benzene. Duncan et al.<sup>3</sup> measured reversible uptake and derived Henry's law constants for 70 wt% H<sub>2</sub>SO<sub>4</sub> at 180, 187 and 195 K and a value at 201 K for 76 wt%. Kane et al.<sup>6</sup> measured uptake in a wetted wall flow reactor and derived H\* parameters for 40, 50, 65, and 75 wt% over a much wider temperature range than Duncan et al.<sup>3</sup> Their data diverge above 80 wt% which they attribute to reactive uptake as suggested by Duncan et al.<sup>2,3</sup> Klassen et al.<sup>7</sup> provide Knudsen cell uptake derived data for 48.7 to 78.3 H<sub>2</sub>SO<sub>4</sub> wt% between 210 and 240 K that are generally consistent with that of Kane et al.<sup>6</sup> Imamura and Akiyoshi<sup>5</sup> report wetted wall flow reactor H\* measurements at 230 K for 50 and 60 wt%, 250 K for 60, 69 and 76 wt%, and 270 K for 76 and 79 wt%; their data diverges a factor of 2 to 4 from that of Kane et al.<sup>6</sup> and Klassen et al.<sup>7</sup>
- Equally weighted data sets from Kane et al.<sup>6</sup> and Klassen et al.<sup>7</sup> were combined and fit to generate the recommended parameterization. Two points for the solubility of acetone in water at 298 K and 273 K (Benkelberg et al.<sup>1</sup>) were included to improve the extrapolation to low wt% solutions. The data points from Imamura and Akiyoshi<sup>5</sup> were not included because they were inconsistent with the other data and have a very different temperature dependence. The few data points from Duncan et al.<sup>2,3</sup> are also inconsistent with the other data and were not included in the parameterization. Using a rotating wetted-wall flow reactor Esteve and Nozière<sup>4</sup> measured H\* coefficients at 298 ± 3K for 89.4, 85, 80.8 73.9 and 70 wt% H<sub>2</sub>SO<sub>4</sub>, reporting values of 840, 650, 500, and 320 M atm<sup>-1</sup>, respectively. These data are not included in the recommended parameterization since the temperature/wt% ranges they cover are unlikely to occur in the atmosphere.
- Williams et al.<sup>8</sup> performed Knudsen cell H\* measurements on the effect of 0.1 M ethanol on the uptake of acetone by 38.4 to 75.0 wt% H<sub>2</sub>SO<sub>4</sub> at temperatures between 217.6 and 238.5 K, corresponding to data points previously reported by Kane et al. and Klassen et al. Their data indicated that the added ethanol had "no significant effect" on the solubility of acetone for comparable ethanol free measurements.

  - (2) Shi, Q.; Davidovits, P.; Jayne, J. T.; Kolb, C. E.; Worsnop, D. R. Kinetic model for reaction of ClONO<sub>2</sub> with H<sub>2</sub>O and HCl and HOCl with HCl in sulfuric acid solutions. *J. Geophys. Res.* **2001**, *106*, 24259-24274.
- 16. HBr in H<sub>2</sub>SO<sub>4</sub>•mHNO<sub>3</sub>•nH<sub>2</sub>O(l).** Experimental data for HBr solubility is provided by Williams et al.<sup>7</sup> Abbatt,<sup>1</sup> Abbatt and Nowak,<sup>2</sup> Kleffman et al.,<sup>4</sup> and Behr et al.<sup>3</sup> Data from time-dependent uptake measurements and from vapor pressure measurements are in good agreement after correcting for the fact that for some of the vapor pressure measurements the HBr concentration in solution was high enough to increase the acidity and thereby decrease the HBr solubility. By comparing pairs of data points with different HBr concentrations (from the same experiment), an average correction factor was obtained. The correction factor was used to correct the vapor pressure data of Williams et al.,<sup>7</sup> Abbatt and Nowak,<sup>2</sup> and Kleffmann et al. to zero effective HBr concentration. (This is different than the approach taken in Kleffmann et al. of using a “corrected” H<sub>2</sub>SO<sub>4</sub> wt%. However, the resulting parameterization is very similar to the one in Kleffmann et al.<sup>4</sup>) The time-dependent uptake data of Williams et al.<sup>7</sup> and Abbatt,<sup>1</sup> and the molecular beam uptake data of Behr et al.<sup>3</sup> did not require correction. All of the experimental data have been fit to obtain the recommended parameterization as a function of H<sub>2</sub>SO<sub>4</sub> wt% and temperature.
- Agreement between this parameterization and the updated activity coefficient model of Massucci et al.<sup>6</sup> (and <http://www.hpc1.uea.ac.uk/~e770/aim.html>) is good for >60 wt%, but not very good at lower H<sub>2</sub>SO<sub>4</sub> wt%, particularly at low temperatures. Therefore, this parameterization is recommended for calculating HBr Henry’s law solubilities.
- The only data for HBr solubilities in ternary solutions is from Kleffmann et al.<sup>4</sup> The data do not agree well with the updated activity coefficient in Massucci et al.<sup>4</sup> or with the older activity coefficient model in Luo et al.<sup>5</sup> Until further information becomes available, the recommendation is to use the parameterization for ternary solutions given in Kleffmann et al.<sup>4</sup>

- 17. HOBr in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** HOBr solubility measurements have been reported from coated wall flow reactor uptake studies by Waschewsky and Abbatt<sup>3</sup> and Hanson<sup>1</sup> and from Knudsen cell uptake studies from Iraci et al.<sup>2</sup> Although they were performed in different temperature ranges, extrapolations of Hanson’s higher temperature data to the temperature range investigated by Waschewsky and Abbatt predicted much higher HOBr solubility than they measured. Iraci et al. subsequently measured HOBr uptake over both of the temperature ranges covered in the prior experiments. Their data agreed well with data from Waschewsky and Abbatt<sup>3</sup> at lower temperatures (213–238 K) but fall far below Hanson’s higher (250–270 K) temperature measurements. The Iraci et al. measurements were performed at ~45, 55, 61 and 70 wt% H<sub>2</sub>SO<sub>4</sub> and investigated over the temperature range from 201 to 252 K. Their results, like the earlier studies, indicate that

the dependence of H\* on acid concentration is relatively weak. For H<sub>2</sub>SO<sub>4</sub> acid wt% from 55 to 75, H\* is well described by:  $\log H^* = (2349 \pm 280)/T - (5.27 \pm 1.24)$ . Their ~45 wt% data are fit by:  $\log H^* = (3665 \pm 270)/T - (10.63 \pm 1.23)$ .

- 18. SO<sub>2</sub> in H<sub>2</sub>SO<sub>4</sub>•nH<sub>2</sub>O(l).** Room temperature vapor pressure measurements reviewed by Hayduk et al.<sup>1</sup> and bubble train reactor uptake measurements by Rattigan et al.<sup>4</sup> for 0–70 wt% H<sub>2</sub>SO<sub>4</sub> agree very well. Langenberg et al.<sup>2</sup> used a novel capillary gas chromatography technique to deduce H\* values for 41–83 wt% H<sub>2</sub>SO<sub>4</sub> over a temperature range of 193–242 K. The recommended parameterization is a fair fit to the Rattigan et al. and Langenberg et al. data sets and allows reasonable extrapolation over the full range of atmospheric temperatures. Note that the Langenberg et al.<sup>2</sup> data is in mol/kg-bar units and was converted to mole/l units using the density parameterization of Myhre et al.<sup>3</sup>

Uncertainty Classes:

- I—Better than 10%
  - II—10% to 50%
  - III—50% to 100%
  - IV—Factor of 2 to factor of 10
  - V—Factor of 10 to factor of 100
  - VI—Greater than a factor of 100
- 

## 5.22 Notes to Table 5-7

### Note 1: Inorganic Gases

[Back to Table](#)

- N<sub>2</sub>O. Measurements at 36.13‰ NaCl using a microgasometric technique.<sup>5</sup> Data taken from the IUPAC evaluation.<sup>7</sup>
- CO. The two published reports on the solubility of CO into salt water were evaluated by Wiesenburg,<sup>6</sup> who concluded that the data of Douglas<sup>1</sup> were significantly more reliable than those of Schmidt.<sup>3</sup> Those data were fit to a function of temperature and salinity. The present recommendation takes this function, calculates the values for 35‰ salinity, and fits those results to a two-parameter equation. A three parameter fit over the temperature range 274–303 K yields  $\ln H = -179.224 + 8620/T + 25.13\ln(T)$ .
- CO<sub>2</sub>. Published data on the solubility of CO<sub>2</sub> into salt water were evaluated by Weiss,<sup>4</sup> who also carried out some confirmatory measurements. The extensive results of Murray and Riley<sup>2</sup> were accepted and fit as a function of temperature and salinity. The present recommendation for seawater takes the calculated values for 35‰ salinity and the newer values for 35.33‰ and fits them to a two-parameter equation over the indicated temperature range. A three parameter fit over the temperature range 272–313 K yields  $\ln H = -157.779 + 8810/T + 21.88\ln(T)$ .

- CH<sub>4</sub>. Ostwald coefficients determined in filtered seawater with a salinity of 35‰.<sup>1</sup> Results fit to a linear equation.

- (1) Scharlin, P.; Battino, R. Solubility of  $\text{CCl}_2\text{F}_2$ ,  $\text{CClF}_3$ ,  $\text{CF}_4$ , and  $\text{CH}_4$  in water and seawater at 288.15–303.15 K and 101.325 kPa. *J. Chem. Eng. Data* **1995**, *40*, 167–169.

### Note 3: Fluoromethanes

[Back to Table](#)

- CHF<sub>3</sub>.** Gas solubilities measured at 278, 308, and 338 K and at NaCl concentrations from 0 to 0.0564 mole/mole (0 to 174‰) with a gas absorption unit.<sup>2</sup> Calculated values for 35‰ NaCl taken at each temperature and fitted to a two-parameter equation.
- CF<sub>4</sub>.** Ostwald coefficients determined in filtered seawater with a salinity of 35‰.<sup>1</sup> Results fit to a linear equation.
- (1) Scharlin, P.; Battino, R. Solubility of  $\text{CCl}_2\text{F}_2$ ,  $\text{CClF}_3$ ,  $\text{CF}_4$ , and  $\text{CH}_4$  in water and seawater at 288.15–303.15 K and 101.325 kPa. *J. Chem. Eng. Data* **1995**, *40*, 167–169.
- (2) Zheng, D.-Q.; Guo, T.-M.; Knapp, H. Experimental and modeling studies on the solubility of  $\text{CO}_2$ ,  $\text{CHClF}_2$ ,  $\text{CHF}_3$ ,  $\text{C}_2\text{H}_2\text{F}_4$  and  $\text{C}_2\text{H}_4\text{F}_2$  in water and aqueous NaCl solutions under low pressures *Fluid Phase Equilibria* **1997**, *129*, 197–209.

### Note 4: Fluorochloromethanes

[Back to Table](#)

- CHF<sub>2</sub>Cl.** Gas solubilities measured at 278, 308, and 338 K and at NaCl concentrations from 0 to 0.0564 mole/mole (0 to 174‰) with a gas absorption unit.<sup>4</sup> Calculated values for 35‰ NaCl taken at each temperature and fitted to a two-parameter equation. These values were double-weighted and fit together with the values measured<sup>2</sup> in seawater by a purge-and-trap technique.
- CFCl<sub>3</sub>.** A linear fit to the results of Hunter-Smith, et al.<sup>1</sup> and Ooki and Yokouchi<sup>2</sup> in seawater. The results are in good agreement at low temperatures (<293 K) but diverge at room temperature and above.
- CF<sub>2</sub>Cl<sub>2</sub>, CF<sub>3</sub>Cl.** Ostwald coefficients determined in filtered seawater with a salinity of 35‰.<sup>3</sup> Results fit to a linear equation.

### Note 5: Chloromethanes

[Back to Table](#)

- CH<sub>3</sub>Cl.** From a measurement of the concentration of the substance in a column of seawater at 30.4 or 34.34‰ salinity as a stream of nitrogen is bubbled through.<sup>5,6</sup> Similar results were reported by Elliott and Rowland at 0 and 22°C.<sup>3</sup>
- CH<sub>2</sub>Cl<sub>2</sub>.** From a measurement of the concentration of the substance in a column of seawater at 34.34‰ salinity as a stream of nitrogen is bubbled through<sup>5</sup> combined with values determined in seawater of salinities of 33.1‰ to 36.1‰ by using a purge-and-trap method and an equilibrator.<sup>7</sup>
- CHCl<sub>3</sub>.** Taken from a linear fit to the results of Moore, et al.,<sup>5,6</sup> Hunter-Smith et al.,<sup>4</sup> and Dewulf, et al.<sup>2</sup> The latter were from a study as a function of salinity and the calculated value at 35‰ was used. These data were double-weighted in the fit. A measurement at 25°C with a purge-and-trap/GC method gave a result in close agreement.<sup>8</sup>

**CCl<sub>4</sub>.** A linear fit to the results of Hunter-Smith, et al.,<sup>4</sup> Bullister and Wisegarver,<sup>1</sup> and Dewulf, et al.<sup>2</sup> The latter were from a study as a function of salinity and the calculated value at 35‰ was used. These data were double-weighted in the fit. The Bullister and Wisegarver<sup>1</sup> data were from a study of the solubility as a function of temperature and salinity. Calculated values for 35‰ from a complex expression were used.

### **Table of Contents**

SECTION 6. THERMODYNAMIC PARAMETERS .....	6-1
6.1 Introduction.....	6-1
6.2 Notes to Table 6-2.....	6-22
6.3 Bibliography – Thermodynamic Parameters .....	6-116

### **Tables**

Table 6-1. Glossary of Groupings.....	6-2
Table 6-2. Gas-Phase Entropy and Enthalpy Values at 100 kPa .....	6-3

#### **6.1 Introduction**

Table 6-2 lists selected entropy and enthalpy of formation values at 298 K for a number of atmospheric species. As much as possible, the values were taken from primary evaluations that develop a recommended value from the original studies. Otherwise, the values were selected from the original literature, which is referenced in the table. Often, the enthalpy of formation and the entropy values are taken from different sources, usually due to a more recent value for the enthalpy of formation. The cited error limits are from the original references and therefore reflect often widely varying criteria. Some enthalpy values have been adjusted to reflect the value of a reference compound selected for this table; these are mentioned in the Notes. Values that are calculated or estimated are also indicated in the Notes, along with information on the level of theory. Results other than those recommended are also often mentioned in the Notes, including recommendations from previous versions of this Table. These should provide a better perspective on the selected value. All values in the Table are in SI (Joule) units. In the notes, some values are reported in calorie units (1 cal = 4.184 J).

In order to make the utilization of Table 6-2 more convenient, the species are grouped according to some defining characteristic. Each of these groupings has a number linked to that group in the Table. Each group, in turn, has a linked Note associated with it, in which the group's species are listed sequentially, followed by comments. At the end of each Note, the applicable references are given. Below is a list of these various groups and their group numbers. Formulas are presented in the order: C H O N F Cl Br I S Hg.

**Table 6-1. Glossary of Groupings**

## 6.2 Notes to Table 6-2

**Note 1:** Simple compounds of H and O

[Back to Table](#)

<b>H</b>	Enthalpy value is from the optimization of Ruscic et al. <sup>17</sup> and is almost the same as the CODATA Key Value, <sup>2</sup> but with a smaller error limit. Entropy value from CODATA. <sup>2</sup>
<b>H<sub>2</sub></b>	CODATA Key Value. <sup>2</sup>
<b>O(<sup>3</sup>P)</b>	Enthalpy value is from the optimization of Ruscic et al. <sup>17</sup> CODATA Key Value <sup>2</sup> of $\Delta_fH_{298}^o = 249.18 \pm 0.10 \text{ kJ mol}^{-1}$ was used in previous evaluation. Entropy value is from CODATA.
<b>O(<sup>1</sup>D)</b>	Based on a transition to the weighted midpoint of the O <sup>3</sup> P J-levels. <sup>13</sup>
<b>O<sub>2</sub></b>	CODATA Key Value. <sup>2</sup>
<b>O<sub>2</sub>(<sup>1</sup>Δ<sub>g</sub>)</b>	Spectroscopic value from Huber and Herzberg. <sup>10</sup>
<b>O<sub>2</sub>(<sup>1</sup>Σ<sub>g</sub><sup>+</sup>)</b>	Enthalpy value is from the optimization of Ruscic, et al. <sup>19</sup> Entropy from Gurvich et al. review, which also gave the previously-listed enthalpy of $141.8 \pm 2 \text{ kJ mol}^{-1}$ . <sup>8</sup>
<b>OH</b>	Enthalpy value is an update <sup>17</sup> to the recommendation of the IUPAC Task Group. <sup>18</sup> It is an optimization, based on photoionization measurements. Values based on Birge-Sponer extrapolations of OH vibrational levels are $2.1 \text{ kJ mol}^{-1}$ higher. The entropy is taken from Gurvich et al. <sup>8</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^o = 36.90 \pm 0.16 \text{ kJ mol}^{-1}$ . <sup>3</sup> Uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables ver. 1.20.
<b>H<sub>2</sub>O</b>	The enthalpy and entropy values are the result of an optimization in the Active Thermochemical Tables (ATcT). <sup>16</sup> Previous values of $-241.826 \pm 0.040 \text{ kJ mol}^{-1}$ and $188.835 \pm 0.010 \text{ J mol}^{-1} \text{ K}^{-1}$ are CODATA Key Values. <sup>2</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^o = -239.18 \pm 0.23 \text{ kJ mol}^{-1}$ . <sup>3</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>HO<sub>2</sub></b>	The enthalpy values are from an optimization of a local thermochemical network consisting of 14 experimental and 7 theoretical reaction enthalpies, and grounded in very well established reference enthalpies. <sup>6</sup> Most theoretical values from the literature were rejected in favor of determinations at a higher level of theory. In this study, computed values of $\Delta_fH_{298}^o = 11.88 \pm 0.33 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^o = 14.81 \pm 0.33 \text{ kJ mol}^{-1}$ were obtained from a composite quantum chemical method discussed in the study, roughly $0.5 \text{ kJ mol}^{-1}$ lower than earlier values. The previous Table values, $\Delta_fH_{298}^o = 11.92 \pm 0.22 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^o = 14.85 \pm 0.22 \text{ kJ mol}^{-1}$ , were from an optimization based on both experimental and theoretical data. <sup>18</sup> Previous enthalpy value at 298 K of $13.4 \pm 2.1 \text{ kJ mol}^{-1}$ was based upon a negative ion thermodynamic cycle, <sup>15</sup> which was in good agreement with the photoionization result of $13.8 \pm 3.3 \text{ kJ mol}^{-1}$ . <sup>12</sup> An earlier network optimization of <i>ab initio</i> reaction enthalpies resulted in a value of $\Delta_fH_0^o = 15.09 \pm 0.23 \text{ kJ mol}^{-1}$ . <sup>3</sup> The uncertainty corresponds to the 95% confidence limit.
<b>H<sub>2</sub>O<sub>2</sub></b>	Enthalpy value based on the enthalpy of formation of liquid H <sub>2</sub> O <sub>2</sub> and the enthalpy of vaporization. <sup>20</sup> A CCSD(T) calculation of the atomization energy, employing the cc-pVnZ basis sets (n=T,Q,5,6) led to $\Delta_fH_{298}^o = -32.28 \text{ kcal mol}^{-1}$ and $\Delta_fH_0^o = -30.83 \text{ kcal mol}^{-1}$ . <sup>5</sup>
<b>HO<sub>3</sub></b>	Enthalpy for the reaction HOOOH + FOO → HOOF + HOOO at the CCSD(T)/CBS(Q5) level of theory is $9.50 \text{ kcal mol}^{-1}$ . Adjusted for the Table reference values, this gives the cited enthalpy of formation. The minimum was found to be the <i>trans</i> configuration at the CCSD(T)/CBS(Q5) level of theory, with the <i>cis</i> configuration $0.5 \text{ kcal mol}^{-1}$ higher in energy. <sup>7</sup> Note that the enthalpy values obtained from the atomization energy were higher, due, apparently, to higher order correlation effects. <sup>7</sup> A more recent calculation employing the 2-electron reduced density matrix method suggests that the <i>cis</i> isomer is $1.84 \text{ kcal mol}^{-1}$ higher in energy than the <i>trans</i> isomer with a aug-cc-pVQZ basis set. <sup>9</sup> The selected value is supported by another analysis using the isodesmic reaction HO <sub>2</sub> + FOO → HO <sub>3</sub> + FO which leads to a value of $\Delta_fH_{298}^o = 6.3 \text{ kcal mol}^{-1}$ . <sup>5</sup> An older theoretical study, using both atomization energies and the reaction HOOO + HOH → HOOOH + OH, resulted in $\Delta_fH_{298}^o = 7.1 \pm 2 \text{ kcal mol}^{-1}$ (not adjusted). <sup>4</sup> The enthalpy of formation derived from an estimate of the ionization

energy of HO<sub>3</sub>, which comes from a study of the electron transfer reactions between HO<sub>3</sub><sup>+</sup> and a series of neutral substrates, was Δ<sub>f</sub>H<sub>298</sub><sup>0</sup> = -1±5 kcal mol<sup>-1</sup>.<sup>20</sup> The stability of HO<sub>3</sub> has been supported by a neutralization-reionization mass spectrometry experiment, which led to a lifetime of >1 μs,<sup>1</sup> and an infrared action spectrum, which leads to an upper limit for the HO-O<sub>2</sub> bond strength of 6.12 kcal mol<sup>-1</sup>.<sup>14</sup>

- HO<sub>3</sub>H** CCSD(T) calculation of the atomization energy, employing the cc-pVnZ basis sets (n=T,Q,5,6).<sup>5</sup> Reaction enthalpy for the reaction 2 HOOH → HOOOH + HOH was calculated to be -15.5 kcal mol<sup>-1</sup> using the G2 method, leading to Δ<sub>f</sub>H<sub>298</sub> = -22.7 kcal mol<sup>-1</sup>.<sup>11</sup> Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level gives Δ<sub>f</sub>H<sub>298</sub> = -21.3 kcal mol<sup>-1</sup> and Δ<sub>f</sub>H<sub>0</sub><sup>0</sup> = -19.2±1 kcal mol<sup>-1</sup>.<sup>7</sup>
- HO<sub>4</sub>H** CCSD(T) calculation of the atomization energy, employing the cc-pVnZ basis sets (n = T,Q,5,6).<sup>5</sup>

**Note 2: Water complexes**

[Back to Table](#)

<b>O<sub>3</sub>•H<sub>2</sub>O</b>	Structures were optimized using the QCISD approach, using the 6-311G(2df,2p) and G+ with aug-cc-pVDZ and aug-cc-pVTZ basis sets. Single point calculations were carried out using the CCSD(T) method with the same basis sets. The lowest energy complexes have van der Waals structures, not hydrogen-bonding, with the two terminal oxygens of ozone interacting with the oxygen atom of water. The calculated bond dissociation enthalpy is 1.58 kcal mol <sup>-1</sup> . The structure involving the central oxygen atom of ozone has a slightly weaker bond, but, due to ZPE corrections, a slightly lower enthalpy. <sup>2</sup>
<b>OH•H<sub>2</sub>O</b>	The structure was optimized with A' symmetry at the CCSD(T)/aug-cc-pVTZ level and a binding energy of 5.88 kcal mol <sup>-1</sup> calculated, resulting in the listed formation enthalpy. <sup>3</sup> In another calculation, the binding energy for the hydrogen-bonded complex was calculated by optimizing the structure using the PM3 method followed by HF/6-31G* self-consistent field optimization. A G3 calculation leads to a reaction enthalpy of -4.49 kcal mol <sup>-1</sup> for the formation of the complex. <sup>1</sup>
<b>H<sub>2</sub>O•H<sub>2</sub>O</b>	The enthalpy and entropy values are the result of an optimization in the Active Thermochemical Tables (ATcT). <sup>6</sup>
<b>HO<sub>2</sub>•H<sub>2</sub>O</b>	Derived from the recommended equilibrium constant for the formation of the complex (Table 3-1, Note 4).
<b>OCl•OH<sub>2</sub></b>	Obtained from a dissociation energy of 2.70 kcal mol <sup>-1</sup> , calculated at the MP2//aug-cc-pVTZ level of theory with a quadruple-ζ basic set. Values of 1.70–1.79 kcal mol <sup>-1</sup> were calculated using B3LYP with triple to quintuple-ζ bases sets. B3LYP//aug-cc-pVTZ was also used to calculate BDEs for hydrates with up to six water molecules. <sup>4</sup>
<b>ClO•HOH</b>	Obtained from a dissociation energy of 1.55 kcal mol <sup>-1</sup> , calculated at the MP2//aug-cc-pVTZ level of theory with a quadruple-ζ basic set. Value of 1.06–1.23 kcal mol <sup>-1</sup> were calculated using B3LYP with triple to quintuple-ζ bases sets. B3LYP//aug-cc-pVTZ was also used to calculate BDEs for hydrates with up to six water molecules. <sup>4</sup>
<b>OBr•OH<sub>2</sub></b>	Obtained from a dissociation energy of 3.48 kcal mol <sup>-1</sup> , calculated at the MP2//aug-cc-pVTZ level of theory. A value of 2.54 kcal mol <sup>-1</sup> was calculated using B3LYP, which was also used to calculate BDEs for hydrates with up to four water molecules. <sup>5</sup>
<b>BrO•HOH</b>	Obtained from dissociation energy of 1.70 kcal mol <sup>-1</sup> , calculated at the MP2//aug-cc-pVTZ level of theory. A value of 1.58 kcal mol <sup>-1</sup> was calculated using B3LYP, which was also used to calculate BDEs for hydrates with up to four water molecules. <sup>5</sup>

**Note 3: Simple compounds of N and H**[Back to Table](#)

<b>N(⁴S)</b>	The enthalpy value is the result of an optimization in the Active Thermochemical Tables (ATcT). <sup>9</sup> Previous value of $472.420 \pm 0.050 \text{ kJ mol}^{-1}$ derived from a PFI-PEPICO TOF study. <sup>10</sup> Entropy from CODATA Key Values. <sup>3</sup>
<b>N₂</b>	CODATA Key Values. <sup>3</sup>
<b>NH</b>	Enthalpy from review of Anderson. <sup>1</sup> Entropy and enthalpy difference ( $0.05 \text{ kJ mol}^{-1}$ ) from JANAF. <sup>2</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = 359.17 \pm 0.17 \text{ kJ mol}^{-1}$ . <sup>4</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20. <sup>9</sup>
<b>NH₂</b>	Recommended values from the IUPAC Task Group. <sup>8</sup> Enthalpy is a weighted average of four measurements since 1982. Previous recommendation was $186 \pm 1 \text{ kJ mol}^{-1}$ . <sup>1</sup> Entropy was taken from a computed anharmonic potential surface, <sup>6</sup> and is close to the JANAF value of $194.71 \pm 0.05 \text{ kJ mol}^{-1}$ . <sup>2</sup>
<b>NH₃</b>	CODATA Key Value. <sup>3</sup> The JANAF Tables give $\Delta_f H_0^\circ = -38.91 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -45.90 \text{ kJ mol}^{-1}$ , and $S^\circ = 192.774 \text{ J K}^{-1}\text{mol}^{-1}$ . <sup>2</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = -38.52 \pm 0.26 \text{ kJ mol}^{-1}$ . <sup>4</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>N₂H</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>7</sup>
<b>trans-N₂H₂</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>7</sup> Previous value, $212 \pm 10 \text{ kJ mol}^{-1}$ , taken from the Gurvich et al. review. <sup>5</sup> (The same value was used for the equilibrium mixture.)
<b>cis-N₂H₂</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>7</sup> Previous enthalpy value, $248 \pm 12 \text{ kJ mol}^{-1}$ , based on enthalpy of conversion of the <i>trans</i> to <i>cis</i> isomers, $36 \pm 12 \text{ kJ mol}^{-1}$ . <sup>5</sup>
<b>N₂H₃</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>7</sup>
<b>N₂H₄</b>	Taken from review of Gurvich et al. <sup>5</sup> An enthalpy value of $23.1 \text{ kcal mol}^{-1}$ was obtained using a geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>7</sup>

**Note 4: Simple compounds containing N and O**

[Back to Table](#)

<b>NO</b>	Enthalpy value is an update <sup>7</sup> to the recommendation of the IUPAC Task Group, which is from an optimization based on experimental data. <sup>8</sup> Previous enthalpy value, $91.29 \pm 0.17 \text{ kJ mol}^{-1}$ from review of Anderson. <sup>3</sup> Much of the difference can be ascribed to the change in the enthalpy for N. Entropy from JANAF. <sup>4</sup>
<b>N<sub>2</sub>O</b>	Taken from review of Gurvich et al. <sup>6</sup> The JANAF Tables give $\Delta_f H_0^\circ = 85.48 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 82.05 \text{ kJ mol}^{-1}$ , and $S^\circ = 219.957 \text{ J K}^{-1}\text{mol}^{-1}$ . <sup>4</sup>
<b>NO<sub>2</sub></b>	The enthalpy value is from an optimization based on experimental data. <sup>8</sup> Entropy from Gurvich et al. <sup>6</sup>
<b>NO<sub>3</sub></b>	Enthalpy derived from a molecular beam photofragmentation translational spectroscopic study, adjusted to Table values for O and NO <sub>2</sub> . <sup>5</sup> Entropy from review of Abramowitz, et al. <sup>1</sup>
<b>N<sub>2</sub>O<sub>3</sub></b>	Taken from review of Gurvich et al. <sup>6</sup> The JANAF Tables give $\Delta_f H_0^\circ = 89.6 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 82.8 \text{ kJ mol}^{-1}$ , and $S^\circ = 308.539 \text{ J K}^{-1}\text{mol}^{-1}$ . <sup>4</sup>
<b>N<sub>2</sub>O<sub>4</sub></b>	Taken from review of Gurvich et al. <sup>6</sup> The JANAF Tables give $\Delta_f H_0^\circ = 18.7 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 9.1 \text{ kJ mol}^{-1}$ , and $S^\circ = 304.376 \text{ J K}^{-1}\text{mol}^{-1}$ . <sup>4</sup>
<b>N<sub>2</sub>O<sub>5</sub></b>	Selected enthalpy value derived from a third-law calculation on the equilibrium constant for the reaction, $\text{NO}_2 + \text{NO}_3 \leftrightarrow \text{N}_2\text{O}_5$ , presented in Table 3-1, note 11. Entropy value was calculated by Alecu and Marshall, <sup>2</sup> as discussed in Table 3-1. Previous values ( $\Delta_f H_{298}^\circ = 13.3 \text{ kJ mol}^{-1}$ , and $S^\circ = 355.7 \text{ J mol}^{-1}$ ) and enthalpy difference taken from review of Gurvich et al. <sup>6</sup> The JANAF Tables give $\Delta_f H_0^\circ = 12.7 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 11.3 \text{ kJ mol}^{-1}$ , and $S^\circ = 346.548 \text{ J K}^{-1}\text{mol}^{-1}$ . <sup>4</sup>

**Note 5: Compounds containing N, H, and O**

[Back to Table](#)

<b>HNO</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>4</sup> Previous enthalpy, $107.1 \pm 2.5 \text{ kJ mol}^{-1}$ , from review of Anderson. <sup>1</sup> Entropy from Gurvich et al., who cites an enthalpy of $102 \text{ kJ mol}^{-1}$ . <sup>7</sup>
<b>HON</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>4</sup>
<b>NH<sub>2</sub>O</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>4</sup>
<b>NH<sub>2</sub>OH</b>	Calculated using isodesmic reactions at several levels of theory and several basis sets. <sup>12</sup> Previous value of $-9.6 \pm 2.2 \text{ kcal mol}^{-1}$ based on average of theoretical and experimental values. <sup>1</sup> Entropy from Gurvich et al. <sup>7</sup>
<b>HNOH</b>	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. <sup>4</sup>
<b>NH<sub>2</sub>NO<sub>2</sub></b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>13</sup> The previous value, $\Delta_f H_{298}^{\circ} = -26 \pm 10 \text{ kJ mol}^{-1}$ , was based on measurements of the enthalpy of formation of the crystalline substance and an estimated value of the enthalpy of sublimation, $60.7 \pm 10 \text{ kJ mol}^{-1}$ . <sup>7</sup>
<b>HONO</b>	Thermodynamic properties for the equilibrium mixtures of isomers from Gurvich et al. review. <sup>7</sup>

**trans-HONO**

Taken from review of Gurvich et al.<sup>7</sup> Values calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions are  $\Delta_f H_{298}^{\circ} = -18.90 \pm 0.05 \text{ kcal mol}^{-1}$  and  $S^{\circ} = 57.89 \text{ cal K}^{-1} \text{ mol}^{-1}$ .<sup>2</sup>

**cis-HONO** Enthalpy value obtained on basis of enthalpy of conversion of trans-HONO into cis-HONO,  $1.7 \pm 0.4 \text{ kJ mol}^{-1}$ .<sup>7</sup> Values calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions are  $\Delta_f H_{298}^{\circ} = -18.40 \pm 0.05 \text{ kcal mol}^{-1}$  and  $S^{\circ} = 57.64 \text{ cal K}^{-1} \text{ mol}^{-1}$ .<sup>2</sup>

**trans-HOON, hydroperoxynitrene or nitrosyl O-oxide**

The O-O dissociation energy was calculated at the CCSDTQ/aug-cc-pVTZ level of theory as  $39.0 \text{ kJ mol}^{-1}$ . This was corrected to 298 K by  $-5.7 \text{ kJ mol}^{-1}$  to give the selected enthalpy value. The *cis* isomer was calculated to be  $6.4\text{--}8.5 \text{ kJ mol}^{-1}$  less stable.<sup>14</sup>

**HNO<sub>2</sub>, nitryl hydride**

Calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions.<sup>2</sup>

**HONO<sub>2</sub>** Taken from the updated NIST-JANAF Tables.<sup>5</sup>

**cis,cis-HOONO**

Derived from a third-law analysis of the equilibrium constant for  $\text{HO} + \text{NO}_2 \leftrightarrow c,c\text{-HOONO}$  (Table 3-1, Note 1). Previous enthalpy value of  $-5.7 \text{ kcal mol}^{-1}$  and values for the *cis,perp-* and *trans,perp*-HOONO calculated at the MP2 level of theory.<sup>10</sup> A computational

study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets, led to  $\Delta_f H_0^\circ = -6.4 \pm 2.0 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = -15.5 \pm 2.0 \text{ kJ mol}^{-1}$ , and  $S = 271.0 \pm 2.0 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>13</sup>

#### *trans, perp*-HOONO

Derived from the dissociation energy for *t,p*-HOONO and reported molecular constants (Table 3-1, Note 1). Enthalpy values for the *cis,cis*-, *cis,perp*-, and *trans,perp*-HOONO have also been calculated at the MP2 level of theory.<sup>10</sup>

- HO<sub>2</sub>NO<sub>2</sub>** Derived from a third-law analysis of the equilibrium constant for  $\text{HO}_2\text{NO}_2 \leftrightarrow \text{HO}_2 + \text{NO}_2$ .<sup>6</sup> Previous recommended enthalpy value of  $-12.7 \pm 0.6 \text{ kcal mol}^{-1}$  from Regimbal and Mozurkewich.<sup>11</sup> A value of  $\Delta_f H_{298}^\circ = -52.3 \text{ kJ mol}^{-1}$  was obtained from a computational study in which equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.<sup>3</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets, led to  $\Delta_f H_0^\circ = -41.3 \pm 2.4 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = -52.4 \pm 2.4 \text{ kJ mol}^{-1}$ , and  $S = 296.2 \pm 2.0 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>13</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
- NH<sub>4</sub>NO<sub>3</sub>** Enthalpy obtained from a third-law analysis of the sublimation pressure of NH<sub>4</sub>NO<sub>3</sub> over the range 321–360 K. The entropy was calculated from molecular constants taken from the literature.<sup>8</sup> A high-level theoretical calculation, CCSD(T) extrapolated to the aug-cc-pV $\infty$ Z basis set, gives  $\Delta_f H_0^\circ = -221.1 \pm 3 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = -230.6 \pm 3 \text{ kJ mol}^{-1}$ , and  $S = 342.4 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>9</sup>

**Note 6: Compounds with one C and 0-4 H**

[Back to Table](#)

<b>C</b>	CODATA Key Value. <sup>2</sup> The JANAF Tables give $\Delta_fH_0^\circ = 711.2 \text{ kJ mol}^{-1}$ , $\Delta_fH_{298}^\circ = 716.7 \text{ kJ mol}^{-1}$ , and $S^\circ = 158.100 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>1</sup>
<b>CH</b>	Recommendation taken from IUPAC Task Group. <sup>9</sup> Previous recommendation of $\Delta_fH(298 \text{ K}) = 597.37 \pm 1.3 \text{ kJ mol}^{-1}$ was from Gurvich et al. <sup>6</sup> The preferred value corresponds to the theoretical value of Császár et al., <sup>4</sup> which is in agreement with the experimental values but is considered to be of higher accuracy. The entropy was taken from Gurvich et al. <sup>6</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^\circ = 592.62 \pm 0.24 \text{ kJ mol}^{-1}$ . <sup>3</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>CH<sub>2</sub>(<sup>3</sup>B<sub>1</sub>)</b>	Update to the recommendation from IUPAC Task Group. <sup>10</sup> Previous recommendations of $\Delta_fH(298 \text{ K}) = 390.4 \pm 0.8 \text{ kJ mol}^{-1}$ and $S(298 \text{ K}) = 194.90 \text{ J K}^{-1} \text{ mol}^{-1}$ were from experiments of Ruscic et al. <sup>11</sup> The present enthalpy recommendation represents a weighted average of this and other experimental results; the higher uncertainty reflects this and the differences between measurements that relate methylene to methyl and those derived from the dissociation of ketene. A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^\circ = 390.86 \pm 0.29 \text{ kJ mol}^{-1}$ . <sup>3</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>CH<sub>2</sub>(<sup>1</sup>A<sub>1</sub>)</b>	Update to the recommendation taken from IUPAC Task Group. <sup>10</sup> Previous recommendation of $\Delta_fH(298 \text{ K}) = 428.0 \pm 0.8 \text{ kJ mol}^{-1}$ was from Jacox. <sup>7</sup> The preferred value is based on the enthalpy of formation of triplet methylene and a separation between the singlet and triplet states of $3147 \pm 5 \text{ cm}^{-1}$ .
<b>CH<sub>3</sub></b>	Recommendation taken from IUPAC Task Group. <sup>9</sup> Entropy value differs only slightly from previously recommended value of $193.96 \text{ J K}^{-1} \text{ mol}^{-1}$ from Gurvich et al. <sup>6</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^\circ = 149.66 \pm 0.34 \text{ kJ mol}^{-1}$ . <sup>3</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>CH<sub>4</sub></b>	Enthalpy from an active thermochemical tables optimization. <sup>12</sup> Enthalpy from flame calorimetry $-74.48 \pm 0.41 \text{ kJ mol}^{-1}$ used previously. <sup>8</sup> Entropy from Frenkel et al. <sup>5</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^\circ = -66.35 \pm 0.46 \text{ kJ mol}^{-1}$ . <sup>3</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.

**Note 7: Compounds containing one C, 0-4 H, and one or more O**

[Back to Table](#)

<b>CO</b>	CODATA Key Value. <sup>3</sup> Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D - 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_fH_0^\circ = -27.0 \pm 0.2 \text{ kcal mol}^{-1}$ and $\Delta_fH_{298}^\circ = -26.2 \pm 0.2 \text{ kcal mol}^{-1}$ . <sup>12</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^\circ = -114.09 \pm 0.32 \text{ kJ mol}^{-1}$ . <sup>4</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>CO<sub>2</sub></b>	CODATA Key Value. <sup>3</sup> The active thermochemical tables optimization gives $\Delta_fH_{298}^\circ = -393.474 \pm 0.014 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^\circ = -393.108 \pm 0.014 \text{ kJ mol}^{-1}$ . <sup>24</sup> Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D - 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_fH_0^\circ = -93.7 \pm 0.2 \text{ kcal mol}^{-1}$ and $\Delta_fH_{298}^\circ = -93.8 \pm 0.2 \text{ kcal mol}^{-1}$ . <sup>12</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^\circ = -392.98 \pm 0.40 \text{ kJ mol}^{-1}$ . <sup>4</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>HCO</b>	Enthalpy from reversible reactions of I and Br with CH <sub>2</sub> O, <sup>1</sup> using present values for HI and HBr. Entropy taken from Gurvich et al. <sup>13</sup> Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D - 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_fH_0^\circ = 10.4 \pm 0.2 \text{ kcal mol}^{-1}$ and $\Delta_fH_{298}^\circ = 10.5 \pm 0.2 \text{ kcal mol}^{-1}$ . <sup>12</sup>
<b>CH<sub>2</sub>O</b>	Enthalpy at 298 K obtained by using experimental reaction enthalpies taken from the literature. <sup>7</sup> This value was confirmed by three computational approaches involving enthalpies of the same reaction, isodesmic reaction enthalpies, and atomization energies, using a range of high-level computational techniques. The previous value, $\Delta_fH_{298}^\circ = -108.7 \pm 0.50 \text{ kJ mol}^{-1}$ , was taken from review of Gurvich et al., as is the present entropy value and enthalpy difference. <sup>13</sup> A CCSD(T) calculation with the aug-cc-pVnZ (n = D,T,Q,5) basis set extrapolated to the CBS limit gave $\Delta_fH_0^\circ = -104.2 \pm 2.1 \text{ kJ mol}^{-1}$ , $\Delta_fH_{298}^\circ = -107.95 \pm 2.1 \text{ kJ mol}^{-1}$ , and $S = 218.57 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>20</sup> A computation using the focal-point analysis approach resulted in $\Delta_fH_0^\circ = -105.42 \pm 0.33 \text{ kJ mol}^{-1}$ , $\Delta_fH_{298}^\circ = -109.23 \pm 0.33 \text{ kJ mol}^{-1}$ . <sup>5</sup>

### ***trans*-HOCO**

The enthalpy and entropy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.<sup>21</sup> The previous  $\Delta_f H_{298}^{\circ} = -187.9 \pm 2.1$  was obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D-7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit.<sup>12</sup> An earlier computational study using G3 and CBS-QB3 methods gave  $\Delta_f H_{298}^{\circ} = -43.3 \pm 2$  kcal mol<sup>-1</sup>.<sup>10</sup> These results are in agreement with photoionization lower limit of -46.5 kcal mol<sup>-1</sup>.<sup>25</sup>

**cis-HOCO** The enthalpy and entropy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.<sup>21</sup> The previous  $\Delta_f H_{298}^{\circ} = -175.7 \pm 2.1$  was obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D-7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit;  $\Delta_f H_0^{\circ} = -41.0 \pm 0.5$  kcal mol<sup>-1</sup>. (Result presented in text as an energy difference of 2.9 kcal mol<sup>-1</sup> over the *trans* form.)<sup>12</sup> An earlier computational study using G3 and CBS-Qb3 methods gave  $\Delta_f H_{298}^{\circ} = -41.4 \pm 2$  kcal mol<sup>-1</sup>.<sup>10</sup>

**HC(O)O** Enthalpy obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D-7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit.<sup>12</sup> An earlier study using vibrational frequencies calculated at the HF/6-31G(D) level and total energies evaluated at the G2(MP2) level, also making use of isodesmic reactions, gave  $\Delta_f H_{298}^{\circ} = -30$  kcal mol<sup>-1</sup> and the quoted entropy value.<sup>30</sup> A CCSD(T)-CBS (W1U) calculation gives  $\Delta_f H_{298}^{\circ} = -129.4 \pm 12.6$  kJ mol<sup>-1</sup>.<sup>11</sup>

**C(O)OH** Vibrational frequencies calculated at the HF/6-31G(D) level and total energies evaluated at the G2(MP2) level, also making use of isodesmic reactions.<sup>30</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave -41.62 kcal mol<sup>-1</sup>.<sup>27</sup>

**HC(O)OH** Enthalpy taken from NBS Tables,<sup>29</sup> entropy calculated based on structure optimized at MP2/6-31G(D) and frequencies calculated at HF6/31G(D) level.<sup>30</sup> See also discussion of enthalpy in Yu et al.<sup>30</sup>  $\Delta_f H_{298}^{\circ} = -90.5$  kcal mol<sup>-1</sup> also obtained by calculating optimized geometry at the CCSD(T)/aVTZ level with the aug-cc-pVTZ basis set; CCSD(T) energy extrapolated to the CBS limit.<sup>22</sup> Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D-7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of  $\Delta_f H_0^{\circ} = -88.9 \pm 0.4$  kcal mol<sup>-1</sup> and  $\Delta_f H_{298}^{\circ} = -90.7 \pm 0.4$  kcal mol<sup>-1</sup>.<sup>12</sup> Microwave intensity measurements have determined that the *cis* rotamer of HC(O)OH to be  $16.3 \pm 0.4$  kJ mol<sup>-1</sup> higher in energy than the *trans* rotamer.<sup>14</sup>

### ***trans*-and *cis*-HC(O)OO**

Photoelectron spectroscopy of the peroxyformate anion was used to obtain the electron affinity of the peroxyformate radical. Through a thermochemical cycle, this leads to the O-H bond dissociation energy, which combined with the calculated enthalpy of the acid, yields the enthalpy of formation. BDEs for both the *cis* and *trans* conformers of the acid could be determined, both leading to the lower-energy *trans* conformer of the radical.<sup>28</sup>

### ***trans*-HC(O)OOH**

Enthalpy obtained from the calculated heat of an isodesmic reaction, at the G3B3MP2 level of theory.<sup>28</sup> This value is slightly lower than  $\Delta_f H_{298}^{\circ} = -285.3 \pm 2.5$  kJ mol<sup>-1</sup> ( $\Delta_f H_0^{\circ} = -275.7$  kJ mol<sup>-1</sup>) obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D-7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit.<sup>12</sup> The present value was chosen as it is conformer specific; the 0 K value is based on the Feller et al.<sup>12</sup> enthalpy difference.

### ***cis*-HC(O)OOH**

The enthalpy value is derived from the value for the *trans* conformer, which is calculated at the G3B3MP2 level of theory, to be 14.2 kJ mol<sup>-1</sup> lower in energy than the *cis* conformer.<sup>28</sup>

### **CH<sub>2</sub>OO, formaldehyde carbonyl oxide (Criegee intermediate)**

Optimized geometry calculated at the CCSD(T)/aVTZ level with the aug-cc-pVTZ basis set; CCSD(T) energy extrapolated to the CBS limit.<sup>22</sup>

**CH<sub>2</sub>O<sub>2</sub>, dioxirane**

Optimized geometry calculated at the CCSD(T)/aVTZ level with the aug-cc-pVTZ basis set; CCSD(T) energy extrapolated to the CBS limit.<sup>22</sup>

**CH<sub>3</sub>O**

Selection taken from IUPAC Task Group.<sup>23</sup> The recommended enthalpy is a weighted average of the experimental determinations, with an amplified uncertainty for the older gas-phase acidity determinations. The recommendation is supported by one recent high-level theoretical study. This value is significantly higher than that recommended here previously,  $17.15 \pm 3.8$  kJ mol<sup>-1</sup> from the evaluation of Berkowitz et al.,<sup>2</sup> and most other previous recommendations. The recommended entropy is also somewhat different than the previously recommended value of 232.86 J K<sup>-1</sup> mol<sup>-1</sup>.<sup>13</sup> Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of  $\Delta_f H_0^\circ = 7.4$  kcal mol<sup>-1</sup> and  $\Delta_f H_{298}^\circ = 5.5$  kcal mol<sup>-1</sup>.<sup>19</sup>

**CH<sub>3</sub>O<sub>2</sub>**

Based on a re-analysis of previous equilibrium data on  $R + O_2 \leftrightarrow RO_2$  from the same laboratory.<sup>16</sup> In a computational study,  $\Delta_f H_{298}^\circ = 8.8$  kJ mol<sup>-1</sup> was determined using G3B3 and CBS-APNO methods with isodesmic reactions to minimize systematic errors, where the geometry was optimized at the B3LYP/cc-pVTZ+d level of theory. This work also provided the recommended entropy.<sup>6</sup>

**CH<sub>2</sub>OH**

Recommendation taken from IUPAC Task Group.<sup>23</sup> Enthalpy is a weighted average of the most recent experimental studies and a theoretical study, and is in good agreement with all the previous experimental results. (Note that the previous value listed in this Table,  $\Delta_f H_0^\circ = -11.5 \pm 1.3$  kJ mol<sup>-1</sup>, was inadvertently for 0 K.) The entropy value reported by Johnson and Hudgens was accepted and is included here with their error limits.<sup>15</sup> Results of Dóbé, et al.<sup>8</sup> give  $-16.6 \pm 1.3$  kJ mol<sup>-1</sup>. Atomization energies calculated using CCSD(T) with cc-pVnZ (n=D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of  $\Delta_f H_0^\circ = -2.3$  kcal mol<sup>-1</sup> and  $\Delta_f H_{298}^\circ = -3.8$  kcal mol<sup>-1</sup>.<sup>19</sup>

**CH<sub>3</sub>OH•HO<sub>2</sub>**

Taken from review of Gurvich et al.<sup>13</sup> Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of  $\Delta_f H_0^\circ = -45.7$  kcal mol<sup>-1</sup> and  $\Delta_f H_{298}^\circ = -48.3$  kcal mol<sup>-1</sup>.<sup>19</sup>

**CH<sub>3</sub>OH•HO<sub>2</sub>**

Estimated from studies on the decay of HO<sub>2</sub> in the presence of CH<sub>3</sub>OH, with supporting *ab initio* calculations (Table 3-1, Note 5).

**CH<sub>2</sub>OOH**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>27</sup> This radical is unstable to decomposition to CH<sub>2</sub>O + OH.

**CH<sub>3</sub>OOH**

Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)/B3LYP/6-311++G(d,p) level. The dissociation energy into HO<sub>2</sub> and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.<sup>17</sup> This was adjusted to the radical values from the present Table. Reaction enthalpies determined using the G2 method indicated  $\Delta H_{298}^\circ(CH_3OO-H)$  is 1.6 kcal mol<sup>-1</sup> lower than  $\Delta H_{298}^\circ(HOO-H)$ , or 85.9 kcal mol<sup>-1</sup> (359.4 kJ mol<sup>-1</sup>), leading to the previous enthalpy value of  $-132.2$  kJ mol<sup>-1</sup>.<sup>18</sup> An earlier recommended enthalpy value ( $-139.0 \pm 8.1$  kJ mol<sup>-1</sup>) was computed on the assumption that the dissociation energy for ROO-H is  $366 \pm 3$  kJ mol<sup>-1</sup> (Stocker and Pilling, unpublished work).<sup>16</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave  $-30.75$  kcal mol<sup>-1</sup> ( $-128.7$  kJ mol<sup>-1</sup>).

$\text{mol}^{-1}$ ).<sup>27</sup> The entropy and enthalpy difference is from the updated JANAF Table.<sup>9</sup> An entropy value of  $273.4 \text{ J K}^{-1} \text{ mol}^{-1}$  was calculated based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>27</sup> Calculations using the CBS-QB3 and CBS-APNO model chemistries on three isodesmic reactions led to  $\Delta_f H_{98}^{\circ} = -129.5 \pm 0.9 \text{ kJ mol}^{-1}$ .<sup>26</sup>

### CH<sub>3</sub>O<sub>3</sub> and CH<sub>3</sub>O<sub>4</sub>

Bond dissociation energies were calculated for CH<sub>3</sub>OOOCH<sub>3</sub> at the G3B3 and CBS-APNO levels of theory, using isodesmic and bond dissociation work reactions. The molecular geometry was optimized at the B3LYP/cc-pVTZ+d level of theory.<sup>6</sup>

[Back to Table](#)

<b>CH<sub>2</sub>NO</b>	From computed G2 heats of reaction. <sup>11</sup>
<b>NH<sub>2</sub>CO</b>	This is the more stable isomer of CH <sub>2</sub> NO (above), which is formed by the association of CH <sub>2</sub> with NO. The enthalpy and entropy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set. <sup>8</sup> The previous $\Delta_f H_{298}^{\circ} = -15.1 \pm 4$ was from computed G2 heats of reaction. <sup>11</sup>
<b>NCO</b>	Enthalpy from D(H-NCO) = 4.9 ± 0.01 eV, <sup>9</sup> using present value for HNCO. Entropy from Gurvich et al. <sup>6</sup>
<b>HNCO, isocyanic acid</b>	The dissociative photoionization of urea was investigated by iPEPICO. <sup>2</sup> The lowest energy channel, CO(NH <sub>2</sub> ) <sub>2</sub> + hν → NH <sub>3</sub> <sup>+</sup> + HNCO + e <sup>-</sup> , was measured accurately and the appearance energy of the second channel, CO(NH <sub>2</sub> ) <sub>2</sub> + hν → NH <sub>2</sub> + H <sub>2</sub> NCO <sup>+</sup> + e <sup>-</sup> , was measured with somewhat lower precision. These were used together with W1 and CBS-APNO calculations

on three isodesmic reactions for  $\text{CO}(\text{NH}_2)_2$  and two isoelectronic reactions for HNCO to determine the enthalpy values for both HNCO and  $\text{CO}(\text{NH}_2)_2$ . The previous value,  $\Delta_fH_{298}^{\circ} = -104 \pm 12 \text{ kJ mol}^{-1}$  from threshold photodissociation of HNCO by measuring  $\text{NH}(\text{a}^1\Delta)$  threshold and fragment energy, adjusted for the present enthalpy of NH.<sup>12</sup> Entropy from NBS Tables.<sup>14</sup>

### **HCONH<sub>2</sub>, Formamide**

From review of Pedley et al.<sup>10</sup>

**CH<sub>2</sub>NO<sub>2</sub>** Recommendation from the Thermodynamics Research Center Data Series.<sup>5</sup> A calculation of the atomization energy at the G3 level of theory leads to  $\Delta_fH_{298}^{\circ} = 31.5 \text{ kcal mol}^{-1}$ . Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.<sup>7</sup>

**CH<sub>3</sub>NO<sub>2</sub>** Enthalpy from Pedley,<sup>10</sup> entropy from Frenkel et al.<sup>5</sup> Enthalpy value calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions is  $\Delta_fH_{298}^{\circ} = -17.67 \pm 0.27 \text{ kcal mol}^{-1}$ , which becomes  $-17.73 \pm 0.27 \text{ kcal mol}^{-1}$  using the reference enthalpy for *cis*-HONO from this Table.<sup>1</sup> A calculation of the atomization energy at the G3 level of theory leads to  $\Delta_fH_{298}^{\circ} = -17.5 \text{ kcal mol}^{-1}$ . Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.<sup>7</sup> A value of  $\Delta_fH_{298}^{\circ} = -73.2 \text{ kJ mol}^{-1}$  was calculated at the G4 level of theory, making use of isodesmic reactions.<sup>4</sup>

**CH<sub>3</sub>ONO** Taken from review of Stull et al.<sup>13</sup> Enthalpy value calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions is  $\Delta_fH_{298}^{\circ} = -15.64 \pm 0.10 \text{ kcal mol}^{-1}$ , which becomes  $-15.81 \pm 0.10 \text{ kcal mol}^{-1}$  using the reference enthalpy for *cis*-HONO from this Table.<sup>1</sup> A calculation of the atomization energy at the G3 level of theory leads to  $\Delta_fH_{298}^{\circ} = -15.4 \text{ kcal mol}^{-1}$ . Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.<sup>7</sup>

**CH<sub>3</sub>ONO<sub>2</sub>** Enthalpy from Pedley,<sup>10</sup> entropy from Stull et al.<sup>13</sup>

**CH<sub>3</sub>O<sub>2</sub>NO<sub>2</sub>** Equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.<sup>3</sup>

### **(NH<sub>2</sub>)<sub>2</sub>CO, Urea**

The dissociative photoionization of urea was investigated by iPEPICO.<sup>2</sup> The lowest energy channel,  $\text{CO}(\text{NH}_2)_2 + \text{hv} \rightarrow \text{NH}_3^+ + \text{HNCO} + \text{e}^-$ , was measured accurately and the appearance energy of the second channel,  $\text{CO}(\text{NH}_2)_2 + \text{hv} \rightarrow \text{NH}_2 + \text{H}_2\text{NCO}^+ + \text{e}^-$ , was measured with somewhat lower precision. These were used together with W1 and CBS-APNO calculations on three isodesmic reactions for  $\text{CO}(\text{NH}_2)_2$  and two isoelectronic reactions for HNCO to determine the enthalpy values for both HNCO and  $\text{CO}(\text{NH}_2)_2$ . The previous value,  $\Delta_fH_{298}^{\circ} = -245.8 \pm 2.0 \text{ kJ mol}^{-1}$  from Pedley et al.,<sup>10</sup> depended on a value of the sublimation energy that appears to be too low.<sup>2</sup>

**C(NO<sub>2</sub>)<sub>4</sub>** Enthalpy value calculated from the atomization energy at the G3 level of theory. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.<sup>7</sup> (see addition and corrections)

**Note 11:** *Compounds containing two C and 0 - 4 H*

[Back to Table](#)

**C<sub>2</sub>** The enthalpy value is the result of an optimization in the Active Thermochemical Tables (ATcT).<sup>12</sup> The entropy value is from JANAF.<sup>3</sup>

**C<sub>2</sub>H** Enthalpy from review of Berkowitz, Ellison, and Gutman.<sup>1</sup>  $\Delta_f H_f^0 = 134.1 \pm 0.7 \text{ kcal mol}^{-1}$ . Entropy from Gurvich et al.<sup>6</sup> High level *ab initio* calculations result in an enthalpy value of  $567.4 \pm 1.5 \text{ kJ mol}^{-1}$ .<sup>14</sup>

**C<sub>2</sub>H<sub>2</sub>** From the review of Gurvich et al.<sup>6</sup> Pedley gives the enthalpy as  $228.2 \pm 0.7 \text{ kJ mol}^{-1}$ .<sup>10</sup> The JANAF Tables give  $\Delta_f H_f^0 = 227.3 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^0 = 226.7 \text{ kJ mol}^{-1}$ , and  $S^0 = 200.958 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>3</sup> A network optimization of *ab initio* reaction enthalpies results in a value of  $\Delta_f H_f^0 = 228.67 \pm 0.35 \text{ kJ mol}^{-1}$ .<sup>4</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.

**H<sub>2</sub>CC, vinylidene**

Based on a series of negative ion photoelectron spectroscopic measurements combined with proton-transfer kinetics.<sup>5</sup> CCSD(T) calculations, extrapolated to the CBS level, lead to  $\Delta_f H_f^0 = 98.6 \text{ kcal mol}^{-1}$  and  $\Delta_f H_{298}^0 = 98.8 \text{ kcal mol}^{-1}$ .<sup>9</sup>

<b>C<sub>2</sub>H<sub>3</sub></b>	Enthalpy derived from a third-law analysis of the reaction $\text{Cl} + \text{C}_2\text{H}_4 \leftrightarrow \text{HCl} + \text{C}_2\text{H}_3$ . <sup>7</sup> A second-law analysis gives $69.1 \pm 1.6 \text{ kcal mol}^{-1}$ . The recommendation of Tsang is $71.5 \pm 1 \text{ kcal mol}^{-1}$ . <sup>16</sup> See also discussion by Lago and Baer. <sup>8</sup> Negative ion photoelectron spectroscopy combined with proton-transfer kinetics leads to a value of $\Delta_f H_{298} = 71.6 \pm 0.8 \text{ kcal mol}^{-1}$ . <sup>5</sup> A calculation at the HEAT345-Q level of theory gives recommended values of $\Delta_f H_0^\circ = 301.5 \pm 1.3 \text{ kJ mol}^{-1}$ and $\Delta_f H_{298}^\circ = 297.3 \pm 1.3 \text{ kJ mol}^{-1}$ . <sup>15</sup> This enthalpy difference provides the 0 K value in the Table. The entropy value was taken from the evaluation of Tsang. <sup>16</sup>
<b>C<sub>2</sub>H<sub>4</sub></b>	From the review of Gurvich et al. <sup>6</sup> The JANAF Tables give $\Delta_f H_0^\circ = 60.0 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 52.5 \text{ kJ mol}^{-1}$ , and $S^\circ = 219.330 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>3</sup>
<b>C<sub>2</sub>H<sub>5</sub></b>	Enthalpy from review of Berkowitz, Ellison, and Gutman. <sup>1</sup> Entropy from Gurvich et al. <sup>6</sup> Enthalpy of $120.7 \pm 1.0 \text{ kJ mol}^{-1}$ has been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory. $\Delta_f H_0^\circ = 132.3 \pm 1.0 \text{ kJ mol}^{-1}$ . <sup>2</sup> A re-analysis of the thermal decomposition of C <sub>2</sub> H <sub>5</sub> I, making use of calculated molecular parameters, led to a value of $\Delta_f H_{298}^\circ = 124 \pm 3 \text{ kJ mol}^{-1}$ . <sup>13</sup>
<b>C<sub>2</sub>H<sub>6</sub></b>	Enthalpy from flame calorimetry measurement. <sup>11</sup> Entropy from Gurvich et al., <sup>6</sup> who gives $\Delta_f H_{298}^\circ = -84.00 \pm 0.40 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -68.38 \pm 0.40 \text{ kJ mol}^{-1}$ .

**Note 12:** Compounds containing two C, one O, and 1-6 H

[Back to Table](#)

<b>CHCO</b>	Based on the recommended dissociation energy for CH <sub>2</sub> CO of 105.3±2.1 kcal mol <sup>-1</sup> . <sup>1</sup> High level <i>ab initio</i> calculations result in an enthalpy of 173.8±1.5 kJ mol <sup>-1</sup> . <sup>20</sup>
<b>CH<sub>2</sub>CO</b>	From photoionization or CH <sub>2</sub> CO and a subsequent optimization of a local thermochemical network. <sup>17</sup> Calculations on several isodesmic reactions using CBS-QB3, CBS-APNO, and G3 methods led to a value of Δ <sub>f</sub> H <sub>298</sub> <sup>o</sup> = -48.2±2.6 kJ mol <sup>-1</sup> . <sup>18</sup>
<b>CH<sub>3</sub>CO</b>	Recommendation taken from IUPAC Task Group. <sup>16</sup> Enthalpy is a weighted average of the experimental results, with amplified uncertainties assigned to the most negative values. This recommendation is only slightly lower than the value -10.0±1.2 kJ mol <sup>-1</sup> previously recommended here. <sup>1</sup>
<b>C<sub>2</sub>H<sub>2</sub>OH</b>	Calculated from the heat of reactions for OH + C <sub>2</sub> H <sub>2</sub> of -146±10 kJ mol <sup>-1</sup> . <sup>7</sup>
<b>CH<sub>2</sub>C(O)H, vinoxy radical</b>	Enthalpy values calculated at the HEAT345-Q level of theory. <sup>21</sup> Previous enthalpy value an average of the a value obtained from the gas-phase basicity and proton affinity determined by a kinetic method (9.9±3.9 kJ mol <sup>-1</sup> ) and a reexamination of the results of Holmes, et al. <sup>11</sup> on the dissociation of ethyl acetate after electron ionization (15.9±5.6 kJ mol <sup>-1</sup> ). <sup>3</sup> This value is supported by several computational studies. <sup>5,9,10,12</sup> Previous recommendation, 10.5±9.2 kJ mol <sup>-1</sup> , was from an analysis of gas-phase acidity and electron affinity studies. <sup>1</sup> A G3MP2B3 calculation led to Δ <sub>f</sub> H <sub>298</sub> <sup>o</sup> = 13.45 kJ mol <sup>-1</sup> and the selected entropy value. <sup>12</sup>

### CH<sub>3</sub>C(O)H

Enthalpy from Pedley,<sup>15</sup> entropy from Frenkel et al.<sup>6</sup>

### Vinyl alcohol and corresponding radicals (CH<sub>2</sub>CHOH, CH<sub>2</sub>COH, CHCHOH)

Molecular geometry optimized at the B3LYP/6-31G(d,p) level of theory. The enthalpy was determined using CBS-Q, CBS-APNO, and G3 methods with isodesmic reactions to minimize systematic errors. Entropies calculated by using the SMCPs program. The enthalpy values for both conformers of vinyl alcohol are within about 5 kJ mol<sup>-1</sup> the average of the experimental values, which are based on ionization techniques.<sup>4</sup>

**CH<sub>3</sub>CH<sub>2</sub>O** Recommendation taken from IUPAC Task Group.<sup>16</sup> Enthalpy is based on a collision-induced dissociation measurement, which lies between the theoretical results and most of the previous recommendations, including that previously included here, Δ<sub>f</sub>H<sub>298</sub><sup>o</sup> = -15.5±3.3 kJ mol<sup>-1</sup>.<sup>1</sup> Ruscic et al. note that their new preferred value corresponds to an O–H bond dissociation energy for ethanol more in line with that in methanol. Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of Δ<sub>f</sub>H<sub>0</sub><sup>o</sup> = 0.8 kcal mol<sup>-1</sup> and Δ<sub>f</sub>H<sub>298</sub><sup>o</sup> = -2.7 kcal mol<sup>-1</sup>.<sup>13</sup>

### CH<sub>2</sub>CH<sub>2</sub>OH

Calculated from the heat of reaction for the addition of OH to C<sub>2</sub>H<sub>4</sub> of -123±6 kJ mol<sup>-1</sup>.<sup>7</sup> Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of Δ<sub>f</sub>H<sub>0</sub><sup>o</sup> = -3.1 kcal mol<sup>-1</sup> and Δ<sub>f</sub>H<sub>298</sub><sup>o</sup> = -6.2 kcal mol<sup>-1</sup>.<sup>13</sup> The enthalpy of formation was also calculated from a set of isodesmic and isogyric

reactions at the CBS-QB3 level of theory to be  $\Delta_f H_{298}^o = -28.7 \pm 2.2 \text{ kJ mol}^{-1}$ . Calculations with B3LYP/cc-pVTZ were about 6  $\text{kJ mol}^{-1}$  more negative.<sup>2</sup>

### **CH<sub>3</sub>CHOH**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>19</sup> Enthalpy recommended in the review of McMullen and Golden is  $-15.2 \pm 1 \text{ kcal mol}^{-1}$ .<sup>14</sup> Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of  $\Delta_f H_0^o = -9.8 \text{ kcal mol}^{-1}$  and  $\Delta_f H_{298}^o = -13.1 \text{ kcal mol}^{-1}$ .<sup>13</sup>

**C<sub>2</sub>H<sub>5</sub>OH** Taken from review of Gurvich, et al.<sup>8</sup> Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of  $\Delta_f H_0^o = -52.1 \text{ kcal mol}^{-1}$  and  $\Delta_f H_{298}^o = -56.4 \text{ kcal mol}^{-1}$ .<sup>13</sup>

**CH<sub>3</sub>OCH<sub>2</sub>** Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>19</sup> Recommendation in the review of McMullen and Golden, adjusted to allow for present enthalpy of CH<sub>3</sub>COCH<sub>3</sub>, is  $-3 \pm 1 \text{ kcal mol}^{-1}$ .<sup>14</sup>

**CH<sub>3</sub>OCH<sub>3</sub>** Enthalpy from Pedley,<sup>15</sup> entropy from Frenkel et al.<sup>6</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave  $-43.98 \text{ kcal mol}^{-1}$ .<sup>19</sup>

**Note 13: Compounds containing two C, two O, and 1-6 H**

[Back to Table](#)

**(CHO)<sub>2</sub>, glyoxal**

The lowest energy conformer is the *trans* isomer. From the updated JANAF Tables, based on measurements of the heat of combustion.<sup>2</sup>

**cy-(C<sub>2</sub>H<sub>2</sub>O)O, oxiranone (an α-lactone of ethylene oxide)**

*Ab initio* calculations utilizing isodesmic reactions.<sup>9</sup>

**CH<sub>3</sub>CHOOH**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup> This radical is unstable towards dissociation.

**C<sub>2</sub>H<sub>5</sub>O<sub>2</sub>** Based on a re-analysis of previous equilibrium data on R + O<sub>2</sub> ↔ RO<sub>2</sub> from the same laboratory.<sup>5</sup>

**C<sub>2</sub>H<sub>5</sub>OOH** Reaction enthalpy for the reaction CH<sub>3</sub>CH<sub>2</sub>OO + CH<sub>3</sub>OOH → CH<sub>3</sub>CH<sub>2</sub>OOH + CH<sub>3</sub>OO calculated to be 0.5 kcal mol<sup>-1</sup> using the QCISD(T)/6-31G\*\*// MP2/6-31G\* method.<sup>6</sup> Previous enthalpy value (-175.4±12.9 kJ mol<sup>-1</sup>) was computed on the assumption that the dissociation energy for ROO-H is 366±3 kJ mol<sup>-1</sup> (Stocker and Pilling, unpublished work).<sup>5</sup> Pedley gives a value of -198.9±58.7 kJ mol<sup>-1</sup>.<sup>8</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave -38.78 kcal mol<sup>-1</sup>.<sup>12</sup> Calculations using the CBS-QB3 and CBS-APNO model chemistries on three isodesmic reactions led to Δ<sub>f</sub>H<sub>298</sub> = -163.7±0.9 kJ mol<sup>-1</sup>.<sup>11</sup> Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup>

**CH<sub>3</sub>OCO, radical from methyl formate**

An average of two isodesmic reactions calculated at the G3MP2//B3LYP/6-31G(d) level.<sup>10</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave  $\Delta_f H_{298}^{\circ} = -37.87 \text{ kcal mol}^{-1}$ .<sup>12</sup> Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup>

**CH<sub>2</sub>OC(O)H**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup>

**CH<sub>3</sub>OC(O)H, methyl formate**

Enthalpy value taken from review of Pedley.<sup>8</sup> An average of three isodesmic reactions calculated at the G3MP2//B3LYP/6-31G(d) level, supported by G3 and B3LYP calculations gives  $\Delta_f H_{298}^{\circ} = -82.3 \pm 0.49 \text{ kcal mol}^{-1}$ .<sup>10</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave  $\Delta_f H_{298}^{\circ} = -85.87 \text{ kcal mol}^{-1}$ .<sup>12</sup> Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup>

**CH<sub>3</sub>COO** Vibrational frequencies calculated at the HF/6-31G(D) level and total energies evaluated at the G2(MP2) level, also making use of isodesmic reactions.<sup>14</sup>

**CH<sub>2</sub>(OH)CO and CH(OH)C(O)H**

Enthalpy derived from isodesmic reactions calculated by the B3LYP/6-31G(d,p) and G3 methods. Reported results were adjusted for enthalpy values of reference compounds in this Table.<sup>3</sup>

**CH<sub>2</sub>(OH)C(O)H, glycoaldehyde**

Enthalpy derived from isodesmic reactions calculated by the B3LYP/6-31G(d,p) and G3 methods. Reported results were adjusted for enthalpy values of reference compounds in this Table.<sup>3</sup>

**CH<sub>2</sub>C(O)OH**

Enthalpy based on CID studies of the acetate radical anion yielding D(H-CH<sub>2</sub>COOH) =  $95.3 \pm 2.9 \text{ kcal mol}^{-1}$ .<sup>13</sup> Entropy based on vibrational frequencies calculated at the HF/6-31G(D) level.<sup>14</sup> Isodesmic reactions at the G2(MP2) level give  $-243 \text{ kJ mol}^{-1}$ .

**CH<sub>3</sub>C(O)O**

Derived from a hybrid experimental/CBS-Q approach.<sup>7</sup>

**CH<sub>3</sub>C(O)OH, acetic acid**

Enthalpy from Pedley<sup>8</sup>, entropy from Chao.<sup>1</sup>

**CH<sub>2</sub>C(OH)<sub>2</sub>, ethene, 1-diol**

Enthalpy obtained from three isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.<sup>10</sup>

**CH<sub>2</sub>(OH)CH<sub>2</sub>OH, 1,2-ethanediol**

Enthalpy from Pedley,<sup>8</sup> entropy from Frenkel et al.<sup>4</sup>

**C(OH)<sub>2</sub>C(O)H, radical from ethanal, 2-diol**

Calculated from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.<sup>10</sup>

**CH(OH)<sub>2</sub>C(O)H, ethanal, 2-diol**

Calculated from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.<sup>10</sup>

**C(O)HC(O)H, ethanedial (glyoxal)**

From the review of Pedley.<sup>8</sup>

**CH<sub>2</sub>OOCCH<sub>3</sub>**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-

$31\text{G}(\text{d}')$  level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup> This radical is unstable towards decomposition.

### $\text{CH}_3\text{OOCCH}_3$

Enthalpy from updated JANAF Tables, based on calorimetric measurements.<sup>2</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave  $\Delta_f H_{298^\circ} = -29.17 \text{ kcal mol}^{-1}$ .<sup>12</sup> Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>12</sup>

### Note 14: Alkylcarbonate radicals

[Back to Table](#)

#### Alkylcarbonate radials

Formation enthalpies for these short-lived radicals were studied by the CBS-Q method, with geometry optimization at the MP2/6-31G(d) level. Enthalpies from both atomization and bond-separation reactions were calculated. The differences were 4 kJ mol<sup>-1</sup> or less, so the values were averaged for inclusion in the Table. The decomposition of the radicals was investigated by charge-reversal and neutralization-reionization mass spectrometry. For these ROC(O)O radicals, hydrogen-atom migration was important for R = CH<sub>3</sub> and C<sub>2</sub>H<sub>5</sub>, whereas decarboxylation was more important for R = H, *i*-C<sub>3</sub>H<sub>7</sub>, and *t*-C<sub>4</sub>H<sub>9</sub>.<sup>1</sup>

**Note 16: Compounds with two C, one N, and 0-5 O**

[Back to Table](#)

Equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.<sup>3</sup>

### **CH<sub>3</sub>C(O)O<sub>2</sub>NO<sub>2</sub>**

Derived from a hybrid experimental/CBS-Q approach.<sup>5</sup>

### **CH<sub>3</sub>CHN(O)OH**

Enthalpy value calculated from the atomization energy at the G3 level of theory. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.<sup>4</sup>

### **C<sub>2</sub>H<sub>5</sub>NH<sub>2</sub>, ethylamine**

From the review of Pedley.<sup>6</sup> Values of  $\Delta_f H_{298}^\circ = -50.1 \pm 1.5 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = -28.6 \pm 1.5 \text{ kJ mol}^{-1}$  have been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.<sup>2</sup>

### **CH<sub>3</sub>NHCH<sub>3</sub>, dimethylamine**

Fom the review of Pedley.<sup>6</sup>

### **CH<sub>3</sub>CONH<sub>2</sub>, acetamide**

Fom the review of Pedley.<sup>6</sup>

## **Note 17: C<sub>3</sub> hydrocarbons**

[Back to Table](#)

### **C<sub>3</sub>H<sub>4</sub>, propadiene**

Enthalpy from Pedley.<sup>4</sup>

### **C<sub>3</sub>H<sub>4</sub>, propyne**

Enthalpy from Pedley.<sup>4</sup>

### **cy-C<sub>3</sub>H<sub>3</sub>, 3-cyclopropenyl radical**

The 3-cyclopropenium cation was reacted with a series of reagents to establish the ionization energy of the radical as  $6.00 \pm 0.17 \text{ eV}$  or  $578.9 \pm 16.4 \text{ kJ mol}^{-1}$ . This, combined with the enthalpy of formation of the reaction of  $1076.5 \pm 3.3 \text{ kJ mol}^{-1}$ , leads to the reported value. High level G3 and W1 calculation lead to similar values.

### **cy-C<sub>3</sub>H<sub>4</sub>, cyclopropene**

Enthalpy from Pedley.<sup>4</sup>

### **C<sub>3</sub>H<sub>5</sub>**

From a second-law analysis of  $\text{C}_3\text{H}_5 + \text{HBr} \leftrightarrow \text{C}_3\text{H}_6 + \text{Br}$ .<sup>6</sup> A calculation at the HEAT345-Q level of theory gives recommended values of  $\Delta_f H_0^\circ = 180.3 \pm 1.8 \text{ kJ mol}^{-1}$  and  $\Delta_f H_{298}^\circ = 168.6 \pm 1.8 \text{ kJ mol}^{-1}$ .<sup>8</sup> This enthalpy difference provides the 0 K value in the Table.

<b>C<sub>3</sub>H<sub>6</sub></b>	Enthalpy from Pedley <sup>4</sup> , entropy from Chao. <sup>3</sup>
<b>n-C<sub>3</sub>H<sub>7</sub></b>	Enthalpy derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory. <sup>1</sup> Previous value of $\Delta_f H_{298}^o = 100 \pm 2 \text{ kJ mol}^{-1}$ estimated by Tsang. <sup>10</sup>
<b>i-C<sub>3</sub>H<sub>7</sub></b>	From a second-law analysis of iso-C <sub>3</sub> H <sub>7</sub> + HBr $\leftrightarrow$ iso-C <sub>3</sub> H <sub>8</sub> + Br. <sup>7</sup> An enthalpy of $\Delta_f H_{298}^o = 88.5 \pm 1.0 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^o = 106.2 \pm 1.0 \text{ kJ mol}^{-1}$ has been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory. <sup>1</sup>
<b>C<sub>3</sub>H<sub>8</sub></b>	Enthalpy by combustion calorimetry. <sup>5</sup> Entropy by ideal gas properties calculations. <sup>2</sup>

**Note 18:** Compounds containing 3 C 1-8 H, and 1 O

[Back to Table](#)

#### 1 and 2-C<sub>3</sub>H<sub>7</sub>OH

From review of Pedely et al.<sup>10</sup>

**C<sub>2</sub>H<sub>5</sub>CO** CBS-4 and G2(MP2,SVP) methods used to obtain thermodynamic properties. Value listed is recommendation based on theoretical and experimental results. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.<sup>14</sup>

#### C<sub>2</sub>H<sub>5</sub>C(O)H

Enthalpy from Pedley,<sup>10</sup> entropy from Frenkel et al.<sup>5</sup>

#### CH<sub>2</sub>CHOCH<sub>3</sub> and C<sub>3</sub>H<sub>5</sub>O

Methyl vinyl ether and corresponding radicals. Molecular geometry optimized at the B3LYP/6-31G(d,p) level of theory. The enthalpy was determined using CBS-Q, CBS-APNO,

and G3 methods with isodesmic reactions to minimize systematic errors. Entropies calculated by using the SMCPs program.<sup>2</sup>

### **CH<sub>3</sub>C(O)CH<sub>2</sub>**

Enthalpy value an average of the a value obtained from the gas-phase basicity and proton affinity determined by a kinetic method ( $-34.6 \pm 8.4$  kJ mol<sup>-1</sup>) and a reexamination of the results of Holmes et al.<sup>7</sup> on the dissociation of 2-propenyl acetate and acetylacetone after electron ionization ( $-33.1$  and  $-30.3$  kJ mol<sup>-1</sup>).<sup>1</sup> This value is supported by several computational studies.<sup>3,6,8</sup> The previous recommendation,  $-28.1 \pm 3.1$  kJ mol<sup>-1</sup>, was derived from forward and reverse rate constants for the reaction  $\text{CH}_3\text{C}(\text{O})\text{CH}_2 + \text{HBr} \leftrightarrow \text{CH}_3\text{C}(\text{O})\text{CH}_3 + \text{Br}$ .<sup>4</sup> The reverse rate constant requires an extrapolation from high temperature for the reference reaction. An earlier photobromination determination of the reverse reaction results in an enthalpy value of  $-24.3 \pm 5.8$  kJ mol<sup>-1</sup>.<sup>9</sup> Density functional and ab initio calculations at the CBS-QB3 level of theory, using a series of isodesmic reactions, led to  $\Delta_f H_{298}^{\circ} = -24.3 \pm 5.8$  kJ mol<sup>-1</sup>.<sup>3</sup> The entropy value is from G3MP2B3 calculation.<sup>8</sup>

### **CH<sub>3</sub>C(O)CH<sub>3</sub>**

Enthalpy from review of Pedley;<sup>10</sup> entropy value from Frenkel.<sup>5</sup>

### **CH<sub>3</sub>CHOCH<sub>3</sub> and CH<sub>3</sub>CH<sub>2</sub>OCH<sub>2</sub>**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>13</sup>

### **CH<sub>3</sub>CH<sub>2</sub>OCH<sub>3</sub>, methoxyethane (methyl ethyl ether)**

Enthalpy from Pedley et al.<sup>10</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave  $-52.20$  kcal mol<sup>-1</sup>.<sup>13</sup> Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>13</sup>

### **CH<sub>2</sub>CC(O)H, radical from propenal**

Enthalpy obtained from four isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.<sup>11</sup>

### **CH<sub>2</sub>CHCO, radical from propenal**

CBS-4 and G2(MP2,SVP) methods used to obtain thermodynamic properties. Value listed is recommendation based on theoretical and experimental results. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.<sup>14</sup>

### **CH<sub>3</sub>CHCO, methyl ketene**

Reaction enthalpies for two isodesmic reactions were calculated at the CBS-QB3, CBS-APNO, and G3 levels.<sup>12</sup> Preferred values for the reference compounds from this Table were employed.

### **CH<sub>2</sub>CHC(O)H, propenal**

Enthalpy obtained from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.<sup>11</sup>

**Note 19:** *Compounds containing 3 C 1-8 H, and 2 O*

[Back to Table](#)

**C<sub>3</sub>H<sub>5</sub>O<sub>2</sub>** Equilibrium constants for the reaction C<sub>3</sub>H<sub>5</sub> + O<sub>2</sub> ↔ C<sub>3</sub>H<sub>5</sub>O<sub>2</sub> were determined over the temperature range 320–420 K and fit to a van't Hoff plot. Combining the results with previous results led to Δ<sub>r</sub>H<sub>298</sub> = -75.6±2.3 kJ mol<sup>-1</sup> and Δ<sub>r</sub>S = -129.9±3.1 J K<sup>-1</sup>mol<sup>-1</sup>.<sup>5</sup>

**CH<sub>2</sub>CHOOCCH<sub>3</sub>**

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±2.8 kJ mol<sup>-1</sup>, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol<sup>-1</sup>, ranged from ±6.7 to 14 kJ mol<sup>-1</sup>.<sup>6</sup>

**CH<sub>3</sub>CH(OH)CH<sub>2</sub>OH, 1,2-propanediol**

From review of Pedley et al.<sup>4</sup>

**C<sub>3</sub>H<sub>5</sub>OOH** Enthalpy based on calculations made using the CBS-QB3 and CBS-APNO model chemistries on two isodesmic reactions.<sup>8</sup>

**CH<sub>2</sub>OC(O)CH<sub>3</sub> and CH<sub>3</sub>OC(O)CH<sub>3</sub>**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>9</sup>

**CH<sub>3</sub>OCH<sub>2</sub>OCH<sub>3</sub>, dimethoxymethane**

From the review of Pedley et al.<sup>4</sup>

**CH<sub>3</sub>CH<sub>2</sub>OC(O), CH<sub>3</sub>CHOC(O)H, CH<sub>3</sub>CH<sub>2</sub>OC(O)H**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>9</sup>

#### **CH<sub>2</sub>(OH)C(O)CH<sub>3</sub>, hydroxyacetone**

Enthalpy derived from isodesmic reactions calculated by the B3LYP/6-31G(d,p) and G3 methods. Reported results were adjusted for enthalpy values of reference compounds in this Table.<sup>1</sup>

#### **CH<sub>3</sub>CHOOCH<sub>3</sub>**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>9</sup> This radical is unstable towards dissociation

#### **CH<sub>3</sub>CH<sub>2</sub>OOCH<sub>3</sub>**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>9</sup>

#### **(CH<sub>3</sub>)<sub>2</sub>CHOO**

Based on a re-analysis of previous equilibrium data on R + O<sub>2</sub> ↔ RO<sub>2</sub> from the same laboratory.<sup>2</sup>

#### **(CH<sub>3</sub>)<sub>2</sub>COOH**

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>9</sup>

#### **(CH<sub>3</sub>)<sub>2</sub>CHOOH**

Reaction enthalpy for the reaction (CH<sub>3</sub>)<sub>2</sub>CHOO + CH<sub>3</sub>OOH → (CH<sub>3</sub>)<sub>2</sub>CHOOH + CH<sub>3</sub>OO calculated to be 0.6 kcal mol<sup>-1</sup> using the QCISD(T)/6-31G\*\*// MP2/6-31G\* method.<sup>3</sup> Enthalpy calculated using the atomization energy method at the CBS-Q level gave -48.1 kcal mol<sup>-1</sup>.<sup>9</sup> Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.<sup>9</sup>

#### **CH<sub>3</sub>C(OH)<sub>2</sub>C(O)OH**

Enthalpy obtained from three isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.<sup>7</sup>

#### **CH<sub>2</sub>(OH)CH(OH)CH<sub>2</sub>OH, 1,2,3-propanetriol**

Taken from the review of Pedley et al.<sup>4</sup>

#### **CH<sub>2</sub>CHOOCH<sub>3</sub>**

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±2.8 kJ mol<sup>-1</sup>, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol<sup>-1</sup>, ranged from ±6.7 to 14 kJ mol<sup>-1</sup>.<sup>6</sup>

**Note 20:** Compounds containing 3 C, H, N, and O

[Back to Table](#)

**C<sub>3</sub>H<sub>7</sub>NH<sub>2</sub>** Enthalpy derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.<sup>2</sup>

**(CH<sub>3</sub>)<sub>3</sub>N, trimethylamine**

From the review of Pedley et al.<sup>5</sup>

**(CH<sub>3</sub>)<sub>3</sub>NO, trimethylene-N-oxide**

Enthalpy from heat of combustion of solid and estimated sublimation enthalpy.<sup>1</sup>

**C<sub>3</sub>H<sub>7</sub>O<sub>2</sub>NO<sub>2</sub>**

Equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.<sup>3</sup>

**NCC(O)CN, oxopropanedinitrile**

From the updated JANAF Tables, based on calorimetric measurements.<sup>4</sup>

**Note 21: Compounds containing 4 C, H, and O**

[Back to Table](#)

**n-C<sub>4</sub>H<sub>10</sub>** Enthalpy by combustion calorimetry.<sup>7</sup> Entropy by ideal gas properties calculations.<sup>4</sup>

**(CH<sub>3</sub>)<sub>2</sub>CCO, dimethyl ketene**

Reaction enthalpies for three isodesmic reactions were calculated at the CBS-QB3, CBS-APNO, and G3 levels.<sup>9</sup> The preferred value for ketene from this Table was employed.

**(CH<sub>3</sub>)<sub>3</sub>CO, tert-Butyloxyl**

Earlier photoacoustic calorimetry results were combined with redetermined values of the enthalpy of formation and vaporization of di-1,1-dimethylethyl peroxide (using combustion calorimetry, ebulliometry, and heat capacity measurements) to derive this improved enthalpy of formation.<sup>2</sup>

#### (CH<sub>3</sub>)<sub>3</sub>COO

Based on a re-analysis of previous equilibrium data on R + O<sub>2</sub> ↔ RO<sub>2</sub> from the same laboratory.<sup>5</sup>

#### (CH<sub>3</sub>)<sub>3</sub>COOH

Enthalpy based on the gas-phase acidity and electron affinity from a negative ion photoelectron spectral study, leading to a BDE(O-H) of 85±2 kcal mol<sup>-1</sup> (83±2 kcal mol<sup>-1</sup> at 0 K).<sup>1</sup> Reaction enthalpy for the reaction (CH<sub>3</sub>)<sub>3</sub>COO + CH<sub>3</sub>OOH → (CH<sub>3</sub>)<sub>3</sub>COOH + CH<sub>3</sub>OO was calculated to be 1.3 kcal mol<sup>-1</sup> using the QCISD(T)/6-31G\*\*// MP2/6-31G\* method, leading to Δ<sub>f</sub>H<sub>298</sub> = -56.8 kcal mol<sup>-1</sup>.<sup>6</sup>

#### (CH<sub>3</sub>COO)<sub>2</sub>, diacetyl peroxide

From updated JANAF Tables, based on a calorimetric measurement on the liquid and an assumed enthalpy of vaporization.<sup>3</sup>

#### trans-CH<sub>3</sub>CHCHOOCH<sub>3</sub>

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±2.8 kJ mol<sup>-1</sup>, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol<sup>-1</sup>, ranged from ±4.2 to 10.3 kJ mol<sup>-1</sup>.<sup>8</sup>

#### cis-CH<sub>3</sub>CHCHOOCH<sub>3</sub>

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±2.0 kJ mol<sup>-1</sup>, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol<sup>-1</sup>, ranged from ±4.0 to 8.0 kJ mol<sup>-1</sup>.<sup>8</sup>

#### CH<sub>2</sub>C(CH<sub>3</sub>)OOCH<sub>3</sub>

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±1.8 kJ mol<sup>-1</sup>, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol<sup>-1</sup>, ranged from ±3.8 to 7.8 kJ mol<sup>-1</sup>.<sup>8</sup>

#### CH<sub>2</sub>CHCH<sub>2</sub>OOCH<sub>3</sub>

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±1.1 kJ mol<sup>-1</sup>, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol<sup>-1</sup>, ranged from ±3.2 to 7.4 kJ mol<sup>-1</sup>.<sup>8</sup>

**Note 22: Inorganic compounds containing F**

[Back to Table](#)

<b>F</b>	Enthalpy value is from the optimization in the Active Thermochemical Tables (ATcT). <sup>16</sup> CODATA Key Value <sup>4</sup> of $\Delta_fH_{98}^{\circ} = 79.38 \pm 0.30 \text{ kJ mol}^{-1}$ was used in previous evaluation. Entropy value is from CODATA.
<b>F<sub>2</sub></b>	CODATA Key Value. <sup>4</sup>
<b>HF</b>	CODATA Key Value. <sup>4</sup> The active thermochemical tables optimization gives an enthalpy value of $-272.775 \pm 0.24 \text{ kJ mol}^{-1}$ . <sup>17</sup> The most recent NIST-JANAF review gives an enthalpy of $-273.3000 \pm 0.70 \text{ kJ mol}^{-1}$ and an entropy of $173.778 \pm 0.005 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>18</sup> A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_fH_0^{\circ} = -272.82 \pm 0.35 \text{ kJ mol}^{-1}$ . <sup>5</sup> The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
<b>HOF</b>	Enthalpy value at 0 K from a re-evaluation of the photoionization studies, along with the newer enthalpy for OH and a more recent ionization energy for OH. <sup>15</sup> Previous values of $\Delta_fH_{98}^{\circ} = -98.3 \pm 4.2 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^{\circ} = -95.4 \pm 4.2 \text{ kJ mol}^{-1}$ from JANAF review from 1972. <sup>3</sup> A calculation of the isodesmic reaction HOF + OH → FO + H <sub>2</sub> O at the W4.2 level of theory leads to $\Delta_fH_{98}^{\circ} = -87.2 \pm 0.6 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^{\circ} = -84.3 \pm 0.6 \text{ kJ mol}^{-1}$ , in good agreement. <sup>13</sup>
<b>FO</b>	Atomization energy was calculated using the Wn family of computational methods. Small increases in the atomization energy were found going from W2.2 to W4.4. These results led to $\Delta_fH_{98}^{\circ} = 110.58 \pm 0.46 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^{\circ} = 109.96 \pm 0.46 \text{ kJ mol}^{-1}$ . <sup>13</sup> Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to $\Delta_fH_{98}^{\circ} = 110.88 \pm 0.84 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^{\circ} = 110.04 \pm 0.84 \text{ kJ mol}^{-1}$ . <sup>9</sup> These were averaged to give the Table values. The previous table values of $\Delta_fH_{98}^{\circ} = 109 \pm 10 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^{\circ} = 108 \pm 10 \text{ kJ mol}^{-1}$ were from the NIST-JANAF thermochemical tables for the oxygen fluorides <sup>2</sup> and were based on mass spectrometric and thermal decomposition studies of FOF. The atomization energy calculated with CCSD(T) using aug-cc-pVnZ (n=D-6) basis sets, approaching the complete basis set limit, resulted in $\Delta_fH_{98}^{\circ} = 27.9 \pm 0.4 \text{ kcal mol}^{-1}$ and $\Delta_fH_0^{\circ} = 27.6 \pm 0.4 \text{ kcal mol}^{-1}$ . <sup>7</sup> The entropy value is from JANAF. <sup>2</sup>
<b>FOF</b>	NIST-JANAF thermochemical tables for the oxygen fluorides. <sup>2</sup> Enthalpy based on a series of calorimetric studies. Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to $\Delta_fH_{98}^{\circ} = 24.7 \pm 1.3 \text{ kJ mol}^{-1}$ and $\Delta_fH_0^{\circ} = 26.8 \pm 1.3 \text{ kJ mol}^{-1}$ . <sup>9</sup> The atomization energy calculated with CCSD(T) using aug-cc-pVnZ (n=D-6) basis sets, approaching the complete basis set limit, resulted in $\Delta_fH_{98}^{\circ} = 6.6 \pm 0.5 \text{ kcal mol}^{-1}$ and $\Delta_fH_0^{\circ} =$

$7.1 \pm 0.5$  kcal mol $^{-1}$ .<sup>7</sup> An extrapolation of a CCSD(T) calculation with aug-cc-pVTZ and aug-cc-pVQZ basis sets lead to  $\Delta_f H_{298}^o = 24.4 \pm 4$  kJ mol $^{-1}$ .<sup>12</sup>

- OFO** Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to the listed enthalpy.<sup>9</sup> The previous Table values of  $\Delta_f H_{298}^o = 380 \pm 20$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 381 \pm 20$  kJ mol $^{-1}$  were from the NIST-JANAF thermochemical tables for the oxygen fluorides and was based on a calculated value of enthalpy difference between OFO and FOO at 0 K of 356 kJ mol $^{-1}$ .<sup>2</sup> The entropy value is also from the JANAF Table and is based on the earlier computational results.
- FOO** From an analysis of studies of the equilibrium  $F + O_2 \leftrightarrow FOO$  (Table 3-1, Note 10). NIST-JANAF thermochemical tables for the oxygen fluorides, based on several experimental values, primarily from kinetic studies recommends  $\Delta_f H_{298}^o = 25.4 \pm 2$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 27.2 \pm 2$  kJ mol $^{-1}$ .<sup>2</sup> This is also the source of the entropy value. A determination of the atomization energy gave  $\Delta_f H_{298}^o = 5.8 \pm 0.3$  kcal mol $^{-1}$ ,<sup>8</sup> whereas a UCCS DT calculation led to  $\Delta_f H_{298}^o = 6.5 \pm 1$  kcal mol $^{-1}$ .<sup>6</sup> Atomization energy was calculated using the Wn family of computational methods. Significant increases in the atomization energy were found going from W2.2 to W4.4. These results led to  $\Delta_f H_{298}^o = 24.6 \pm 0.7$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 26.4 \pm 0.7$  kJ mol $^{-1}$ .<sup>13</sup> Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to  $\Delta_f H_{298}^o = 26.8 \pm 2.9$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 28.9 \pm 2.9$  kJ mol $^{-1}$ .<sup>9</sup>
- HOOF** Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized through the CCSD(T)/aV(T+d)Z level.<sup>10</sup>
- FOOF** NIST-JANAF thermochemical tables for the oxygen fluorides.<sup>2</sup> Value adopted for enthalpy is that recommended by Lyman<sup>14</sup> based on a calorimetric measurement on the decomposition into  $O_2$  and  $F_2$ . The atomization energy calculated with CCSD(T) using aug-cc-pVnZ ( $n=D-6$ ) basis sets, approaching the complete basis set limit, resulted in  $\Delta_f H_{298}^o = 40.2 \pm 3.8$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 43.9 \pm 3.8$  kJ mol $^{-1}$ .<sup>7</sup> Atomization energy was calculated using the Wn family of computational methods. Significant increases in the atomization energy were found going from W2.2 to W4.4. These results led to  $\Delta_f H_{298}^o = 32.8 \pm 0.75$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 37.24 \pm 0.75$  kJ mol $^{-1}$ .<sup>13</sup> Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to  $\Delta_f H_{298}^o = 26.8 \pm 2.9$  kJ mol $^{-1}$  and  $\Delta_f H_0^o = 31.0 \pm 2.9$  kJ mol $^{-1}$ .<sup>9</sup> An extrapolation of a CCSD(T) calculation with aug-cc-pVTZ and aug-cc-pVQZ basis sets lead to  $\Delta_f H_{298}^o = 34.8 \pm 4$  kJ mol $^{-1}$ .<sup>12</sup>
- FOOOF, for the C<sub>2</sub> conformer**  
Based on an extrapolation of a CCSD(T) calculation with aug-cc-pVTZ and aug-cc-pVQZ basis sets. For the C<sub>s</sub> conformer,  $\Delta_f H_{298}^o = 111.3 \pm 4$  kJ mol $^{-1}$  and  $S = 204.3$  J K mol $^{-1}$  K $^{-1}$ .<sup>12</sup>
- FNO** The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.<sup>20</sup> The previous value,  $\Delta_f H_{298}^o = -65.7$  kJ mol $^{-1}$ , was taken from review of Stull, et al.<sup>19</sup> The JANAF Tables give  $\Delta_f H_0^o = -63.3$  kJ mol $^{-1}$ ,  $\Delta_f H_{298}^o = -65.7$  kJ mol $^{-1}$ , and  $S^o = 248.082$  J mol $^{-1}$  K $^{-1}$ .<sup>3</sup>
- cis, trans-FONO**  
The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.<sup>20</sup> The previous value,  $\Delta_f H_{298}^o = 67$  kJ mol $^{-1}$ , was estimated.<sup>1</sup>
- FNO<sub>2</sub>** The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.<sup>20</sup> The previous value,  $\Delta_f H_{298}^o = -79$  kJ mol $^{-1}$ , was taken from review of Stull et al.<sup>19</sup>

<b>FONO<sub>2</sub></b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>20</sup> The previous value, $\Delta_f H_{298}^{\circ} = 15 \pm 3 \text{ kJ mol}^{-1}$ , was taken from review of Gurvich et al. <sup>11</sup> The JANAF estimate from 1963 gave an enthalpy of $10 \pm 2 \text{ kJ mol}^{-1}$ . <sup>3</sup>
<b>NF<sub>2</sub></b>	Enthalpy value from a reanalysis of the data used by JANAF, combined with the newer enthalpy value for NF <sub>3</sub> . <sup>21</sup>
<b>NF<sub>3</sub></b>	A study of the combustion of rhombic sulfur in NF <sub>3</sub> to generate SF <sub>6</sub> and N <sub>2</sub> using $\Delta_f H_{298}^{\circ}(\text{SF}_6) = -1220.8 \pm 0.8 \text{ kJ mol}^{-1}$ results in the enthalpy of NF <sub>3</sub> . <sup>21</sup>

<b>CF</b>	Thermodynamic properties from Gurvich et al. review. <sup>5</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 243.3 \pm 0.8 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 247.0 \pm 0.8 \text{ kJ mol}^{-1}$ , and $S = 212.9 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup>
<b>CHF</b>	Calculated for the X <sup>1</sup> A' state. Enthalpy from a CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit and entropy from a MP2/aVTZ calculation. <sup>8</sup> Enthalpy obtained using the computed enthalpy of a reaction of the type: CH <sub>2</sub> ( <sup>1</sup> A <sub>1</sub> ) + CH <sub>2</sub> F <sub>2</sub> + 2CH <sub>3</sub> Y → CFY( <sup>1</sup> A <sub>1</sub> ) + 3CH <sub>4</sub> results in $\Delta_f H_{298}^\circ = 146 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. <sup>14</sup> Previous recommendation, $\Delta_f H_{298}^\circ = 143 \pm 13.0 \text{ kJ mol}^{-1}$ , based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations. <sup>11</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 148.9 \pm 1.2 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 149.0 \pm 1.2 \text{ kJ mol}^{-1}$ , and $S = 223.1 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup>
<b>CH<sub>2</sub>F</b>	Derived from the kinetics and equilibria of the iodination reaction CH <sub>3</sub> F + I <sub>2</sub> ↔ CH <sub>2</sub> FI + HI. <sup>10</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-29.0 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>15</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -27.9 \pm 1.6 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -31.2 \pm 1.6 \text{ kJ mol}^{-1}$ , and $S = 232.5 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup> This enthalpy difference was used to calculate the 0 K value in the Table.
<b>CH<sub>3</sub>F</b>	Enthalpies of reaction calculated (and averaged) at the MCG3//MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support. <sup>6</sup> Previous value, $\Delta_f H_{298}^\circ = -238 \pm 8 \text{ kJ mol}^{-1}$ , estimated in review of Rodgers et al. <sup>12</sup> Luo and Benson recommend $-55.9 \pm 1 \text{ kcal/mol}$ . <sup>7</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -228.5 \pm 2.0 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -236.9 \pm 2.0 \text{ kJ mol}^{-1}$ , and $S = 222.5 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup> This enthalpy difference was used to calculate the 0 K value in the Table.
<b>CF<sub>2</sub></b>	Calculated for the X <sup>1</sup> A' state. Enthalpy from a CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit and entropy from a MP2/aVTZ calculation. <sup>8</sup> $\Delta_f H_0^\circ = -46.0 \pm 0.8 \text{ kcal mol}^{-1}$ . Enthalpy obtained using the computed enthalpy of a reaction of the type: CH <sub>2</sub> ( <sup>1</sup> A <sub>1</sub> ) + CH <sub>2</sub> F <sub>2</sub> + 2CH <sub>3</sub> Y → CFY( <sup>1</sup> A <sub>1</sub> ) + 3CH <sub>4</sub> results in $\Delta_f H_{298}^\circ = -196 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. <sup>14</sup> Previous recommendation, $-44.0 \pm 2 \text{ kcal mol}^{-1}$ , based

	on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations. <sup>11</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -193.6 \pm 1.2 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -193.2 \pm 1.2 \text{ kJ mol}^{-1}$ , and $S = 240.6 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup>
<b>CHF<sub>2</sub></b>	Derived from the kinetics and equilibria of the iodination reaction $\text{CH}_3\text{F} + \text{I}_2 \leftrightarrow \text{CH}_2\text{FI} + \text{HI}$ . <sup>10</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-241.2 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>15</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -239.4 \pm 2.6 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -243.0 \pm 2.6 \text{ kJ mol}^{-1}$ , and $S = 255.8 \pm 6.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CH<sub>2</sub>F<sub>2</sub></b>	From review by Rodgers et al. <sup>12</sup> Pedley gives $-452.3 \pm 0.9 \text{ kJ mol}^{-1}$ . <sup>9</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -442.6 \pm 2.0 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -450.5 \pm 2.0 \text{ kJ mol}^{-1}$ , and $S = 246.3 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CF<sub>3</sub></b>	Enthalpy from a simultaneous solution of a thermochemical network for the $\text{CF}_3\text{X}$ species, where X = nil, H, Cl, Br, I, $\text{CF}_3$ , CN. <sup>13</sup> Entropy from recommendation of Gurvich et al. <sup>5</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-465.9 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>15</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -464.8 \pm 1.6 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -467.6 \pm 1.6 \text{ kJ mol}^{-1}$ , and $S = 264.1 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup>
<b>CHF<sub>3</sub></b>	Enthalpy from a simultaneous solution of a thermochemical network for the $\text{CF}_3\text{X}$ species, where X = nil, H, Cl, Br, I, $\text{CF}_3$ , CN. <sup>13</sup> Entropy from recommendation of Gurvich et al. <sup>5</sup> An enthalpy calculation from the atomization energy was obtained starting with a ‘best estimated’ structure from extensive calculations and analysis, followed by CCST with aug-cc-pVQZ and aug-cc-pV5Z basis sets, and CCSD(T) with aug-cc-pVTZ and aug-cc-pVQZ basis sets. Values of $\Delta_f H_0^\circ = -165.18 \text{ kcal mol}^{-1}$ and $\Delta_f H_{298}^\circ = -166.86 \text{ kcal mol}^{-1}$ were obtained. <sup>1</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -687.7 \pm 2.0 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -694.9 \pm 2.0 \text{ kJ mol}^{-1}$ , and $S = 259.2 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup>
<b>CF<sub>4</sub></b>	CODATA Key Value. <sup>3</sup> The JANAF Tables give $\Delta_f H_0^\circ = -927.2 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -933.2 \text{ kJ mol}^{-1}$ , and $S^\circ = 261.419 \text{ J mol}^{-1}$ . <sup>2</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -927.8 \pm 2.0 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -933.8 \pm 2.0 \text{ kJ mol}^{-1}$ , and $S = 260.9 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>4</sup>

**Note 24:** *Compounds containing one C and one or more F and O*

[Back to Table](#)

**CFH<sub>2</sub>O and CFH<sub>2</sub>OH**

The enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.<sup>16</sup>

**FCO** The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.<sup>14</sup> The previous  $\Delta_f H_{298}^{\circ} = -174.1 \pm 2$  was from a CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit.<sup>13</sup> The entropy value is from from a MP2/aVTZ calculation.<sup>13</sup> The decomposition rate constant for FCO → F + CO,<sup>9</sup> combined with the rate constant k =  $2.4 \times 10^{-22}$  cm<sup>6</sup> s<sup>-1</sup><sup>18</sup> for the reverse reaction, results in an upper limit of  $\Delta_f H_{298}^{\circ} < -153.1$  kJ mol<sup>-1</sup>.<sup>9</sup> A. CCSD(T) calculation gives  $\Delta_f H_{298}^{\circ} = -42.0 \pm 0.5$  kcal mol<sup>-1</sup>.<sup>4</sup>

**FCO<sub>2</sub>, fluoroformyloxy radical**

Calculated at the CCSD(T) level of theory. CFO value from same work is  $-42.0 \pm 0.5$  kcal mol<sup>-1</sup>, which differs from value in Table.<sup>4</sup>

**CHFO** The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.<sup>14</sup> The previous  $\Delta_f H_{298}^{\circ} = -381.2 \pm 2$  was from a CCSD(T) calculation with the aug-cc-pVnZ (n = D,T,Q,5) basis set extrapolated to the CBS limit.<sup>13</sup> The entropy value is from from a MP2/aVTZ calculation.<sup>13</sup> The earlier enthalpy value,  $-91.6$  kcal mol<sup>-1</sup>, was from an G2(MP2) calculation,<sup>17</sup> and the earlier entropy was from Gurvich et al.<sup>8</sup>

**CF<sub>2</sub>HFO and CF<sub>2</sub>HOH**

The enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.<sup>16</sup>

**CF<sub>2</sub>O** The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set,<sup>14</sup> supported by several earlier computational studies discussed in that paper.<sup>3,7,13</sup> The previous  $\Delta_f H_{298}^{\circ} = -623.8 \pm 5.9$  was a lower limit from a photoionization study.<sup>1</sup> Entropy from Gurvich et al.<sup>8</sup> Pedley review gives an enthalpy value of  $-639.8 \pm 1.4$  kJ

$\text{mol}^{-1}$ .<sup>15</sup> A CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit gave  $\Delta_f H_0^\circ = -143.9 \pm 0.5 \text{ kcal mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = -144.7 \pm 0.5 \text{ kcal mol}^{-1}$ , and  $S = 61.87 \text{ cal K}^{-1}\text{mol}^{-1}$ .<sup>13</sup>

<b>CF<sub>3</sub>O</b>	Re-analysis of data of Batt and Walsh, using new value for CF <sub>2</sub> O. <sup>1</sup> The enthalpy of formation, $\Delta_f H_{298}^\circ = -154.5 \text{ kcal mol}^{-1}$ based on an isodesmic reaction calculated at the MP2/6-31G(d,p) level of theory. <sup>16</sup>
<b>CF<sub>2</sub>O<sub>2</sub></b>	Determined on the basis of extensive ab initio calculations. <sup>11</sup> Isomeric forms F <sub>2</sub> COO and FC(=O)OF are calculated to have enthalpies of -60 and -104 kcal mole <sup>-1</sup> , respectively.
<b>CF<sub>3</sub>O<sub>2</sub></b>	Two values for the C-O bond dissociation energy in CF <sub>3</sub> O <sub>2</sub> are given in Lightfoot, et al., -144±3.3 and -141±10 kJ mol <sup>-1</sup> at 0 K and adjusted to 298 K. <sup>12</sup> The value given is an average of the two resulting enthalpies.
<b>CF<sub>3</sub>OH</b>	Proton affinity obtained by using transitional energy threshold measurements on protonated trifluoromethanol. This was used in a thermochemical cycle to derive the enthalpy of formation. <sup>6</sup> Previous value was based on a photoionization study, where a lower limit of $\Delta_f H_{298}^\circ > -908.8 \pm 0.9 \text{ kJ mol}^{-1}$ was presented. <sup>2</sup> The enthalpy of formation, $\Delta_f H_{298}^\circ = -933.4 \text{ kJ mol}^{-1}$ , based on an isodesmic reaction calculated at the MP2/6-31G(d,p) level of theory. <sup>16</sup>
<b>CF<sub>3</sub>OF</b>	Based on photoionization of CF <sub>3</sub> OF and an analysis of the CF <sub>3</sub> <sup>+</sup> and CF <sub>2</sub> O <sup>+</sup> fragments. <sup>2</sup> A G2 calculation led to an enthalpy of -774.5 kJ mol <sup>-1</sup> . <sup>5</sup>

#### CH<sub>2</sub>FOOH, CHF<sub>2</sub>OOH, and CF<sub>3</sub>OOH

Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)//B3LYP/6-311++G(d,p) level. The dissociation energy into HO<sub>2</sub> and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.<sup>10</sup> This was adjusted to the radical values from the present Table.

**CH<sub>2</sub>CHF** Enthalpy from review of Pedley.<sup>13</sup>

**CH<sub>2</sub>CH<sub>2</sub>F and CH<sub>3</sub>CHF**

Enthalpy from photobromination studies.<sup>11</sup> Entropy determined at the UHF/6-31G\* level of theory.<sup>2</sup>

**CH<sub>3</sub>CH<sub>2</sub>F** Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous value of  $\Delta_fH_{298}^{\circ} = -278.2 \pm 1.7 \text{ kJ mol}^{-1}$  was based on enthalpies of reaction calculated at the MCG3//MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction and

averaged. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support.<sup>8</sup> Previous entropy  $S^\circ = 265.1 \text{ J mol}^{-1}$  from Gurvich et al. review.<sup>6</sup>

**CH<sub>2</sub>CF<sub>2</sub>** Enthalpy from review of Pedley.<sup>13</sup>

**CH<sub>3</sub>CHF<sub>2</sub>, 1,1-difluoroethane**

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous value of  $\Delta_f H_{298}^\circ = -497.0 \pm 8.3 \text{ kJ mol}^{-1}$  was from a review by Pedley.<sup>13</sup>

**anti- and gauche-CH<sub>2</sub>FCH<sub>2</sub>F, 1,2-difluoroethanes**

The conformationally averaged values are  $\Delta_f H_{298}^\circ = -446.9 \pm 3.4 \text{ kJ mol}^{-1}$  and  $S^\circ = 296.8 \pm 2.8 \text{ J mol}^{-1}$ . Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous enthalpy of  $\Delta_f H_{298}^\circ = -232 \pm 25 \text{ kJ mol}^{-1}$  was based on an analysis of the thermal elimination of HF from CH<sub>2</sub>FCH<sub>2</sub>F, which led to a C-C bond dissociation energy of  $88 \pm 2 \text{ kcal mol}^{-1}$ .<sup>7</sup>

**CH<sub>2</sub>FCHF** Thermodynamic properties determined at the UHF/6-31G\* level, utilizing isodesmic/homodesmic reactions for enthalpy of formation.<sup>4</sup>

**CHF<sub>2</sub>CH<sub>2</sub>** Thermodynamic properties determined at the UHF/6-31G\* level, utilizing isodesmic/homodesmic reactions for enthalpy of formation.<sup>2</sup>

**CH<sub>3</sub>CF<sub>2</sub>** The dissociation energy of CH<sub>3</sub>CF<sub>2</sub>-H of  $99.5 \pm 1 \text{ kcal mol}^{-1}$  was derived from a study of the equilibrium CH<sub>3</sub>CF<sub>2</sub>H + I<sub>2</sub>  $\leftrightarrow$  CH<sub>3</sub>CF<sub>2</sub>I + HI.<sup>14</sup> Entropy calculated from molecular properties computed at the UHF/6-31\* level of theory.<sup>3</sup>

**CH<sub>3</sub>CHF<sub>2</sub>** Taken from a Thermodynamics Research Center review.<sup>1</sup>

**anti- and gauche-CH<sub>2</sub>FCHF<sub>2</sub>, 1,1,2-trifluoroethanes**

The conformationally averaged values are,  $\Delta_f H_{298}^\circ = -661 \pm 3.4 \text{ kJ mol}^{-1}$  and  $S^\circ = 316.9 \pm 2.0 \text{ J mol}^{-1}$ . Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous value of  $\Delta_f H_{298}^\circ = -665 \pm 4 \text{ kJ mol}^{-1}$  was based on the heat of hydrogenation of CF<sub>2</sub>CFCI.<sup>9</sup> Pedley gives an enthalpy value of  $-730.7 \pm 20.8 \text{ kJ mol}^{-1}$ .<sup>13</sup>

**CH<sub>2</sub>CF<sub>3</sub>** The dissociation energy of CF<sub>3</sub>CH<sub>2</sub>-H was derived from a study of the equilibrium CF<sub>3</sub>CH<sub>3</sub> + I<sub>2</sub>  $\leftrightarrow$  CF<sub>3</sub>CH<sub>2</sub>I + HI.<sup>16</sup> Entropy calculated from molecular properties computed at the UHF/6-31\* level of theory.<sup>2</sup>

**CH<sub>3</sub>CF<sub>3</sub>, 1,1,1-trifluoroethane**

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-

pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous values of  $\Delta_f H_{298}^{\circ} = -445.6 \pm 1.7 \text{ kJ mol}^{-1}$  and  $S^{\circ} = 287.3 \text{ J mol}^{-1}$  were from the Thermodynamics Research Center review.<sup>1</sup> Pedley review gives  $-744.6 \pm 1.7 \text{ kJ mol}^{-1}$ .<sup>13</sup>

**CF<sub>2</sub>CF<sub>2</sub>** Enthalpy from review of Pedley.<sup>13</sup>

**anti- and gauche-CHF<sub>2</sub>CHF<sub>2</sub>, 1,1,2,2-tetrafluoroethanes**

The conformationally averaged values are  $\Delta_f H_{298}^{\circ} = -877.6 \pm 3.8 \text{ kJ mol}^{-1}$  and  $S^{\circ} = 323.2 \pm 4.7 \text{ J mol}^{-1}$ . Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous  $\Delta_f H_{298}^{\circ} = -860 \pm 24 \text{ kJ mol}^{-1}$  calculated based on the C-C bond strength estimate of  $91.4 \pm 3.7 \text{ kcal mol}^{-1}$ .<sup>10</sup> Previous  $S^{\circ} = 320.3 \text{ J mol}^{-1}$  from Thermodynamics Research Center review.<sup>5</sup>

**CHFCF<sub>3</sub>** Entropy calculated from molecular properties computed at the UHF/6-31\* level of theory. Enthalpy derived from isodesmic reactions and adjusted down by 2  $\text{kJ mol}^{-1}$  to reflect the enthalpy value for CH<sub>2</sub>FCF<sub>3</sub> in this Table.<sup>4</sup>

**CH<sub>2</sub>FCF<sub>3</sub>, 1,1,1,2-tetrafluoroethane**

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous values of  $\Delta_f H_{298}^{\circ} = -896 \pm 8 \text{ kJ mol}^{-1}$  (estimated) and  $S^{\circ} = 316.2 \text{ J mol}^{-1}$  were from the Thermodynamics Research Center review.<sup>1</sup>

**CF<sub>2</sub>CF<sub>3</sub>** A dissociation energy of C<sub>2</sub>F<sub>5</sub>-I of  $52.5 \pm 1 \text{ kcal mol}^{-1}$  was derived from a study of the reaction of pentafluoroethyl iodide with HI.<sup>17</sup>

**CHF<sub>2</sub>CF<sub>3</sub>, pentafluoroethane**

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup> Previous values of  $\Delta_f H_{298}^{\circ} = -1105 \pm 5 \text{ kJ mol}^{-1}$  and  $S^{\circ} = 333.7 \text{ J mol}^{-1}$  were from the Thermodynamics Research Center review.<sup>1</sup> Pedley review gives an enthalpy value of  $-1100.4 \pm 4.1 \text{ kJ mol}^{-1}$ .<sup>13</sup>

**C<sub>2</sub>F<sub>6</sub>, hexafluoroethane**

Enthalpy from a simultaneous solution of a thermochemical network for the CF<sub>3</sub>X species, where X = nil, H, Cl, Br, I, CF<sub>3</sub>, CN.<sup>15</sup> Entropy from recommendation of Chen, et al.<sup>1</sup> A study in which conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect

led to  $\Delta_f H_{298}^\circ = -1339.8 \pm 3.2 \text{ kJ mol}^{-1}$  and  $S^\circ = 331.0 \pm 1.5 \text{ J mol}^{-1}$ . The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.<sup>12</sup>

**Note 27:** Compounds containing two C and one or more F and O

[Back to Table](#)

### $\text{CH}_2\text{FCH}_2\text{OH}$

The enthalpy of formation was calculated from a set of isodesmic and isogyric reactions at the CBS-QB3 level of theory and refers to the *gauche* configuration. Calculations with B3LYP/cc-pVTZ were in good agreement.<sup>2</sup>

### **CH<sub>2</sub>FCOOH**

The enthalpy of formation was calculated from a set of isodesmic and isogyric reactions at the CBS-QB3 level of theory. Calculations with B3LYP/cc-pVTZ were in good agreement.<sup>2</sup>

### **CF<sub>3</sub>CO**

CBS-4 and G2(MP2,SVP) methods used to obtain thermodynamic properties. In addition, enthalpy was derived from isodesmic reaction calculations. Value listed is recommendation based on theoretical and experimental results. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.<sup>8</sup>

### **CF<sub>3</sub>C(O)H**

Thermodynamic properties calculated at the G2(MP2(full)//MP2(full)/6-31G(d) level of theory. Enthalpy from atomization energy and entropy calculated treating internal rotations as harmonic oscillators. Similar values obtained at the CBS-4//HF/3021G\* level.<sup>8</sup>

### **CH<sub>3</sub>C(O)F, acetyl fluoride**

Enthalpy value from review of Pedley.<sup>4</sup>

### **CF<sub>3</sub>C(O)F**

Thermodynamic properties calculated for five isodesmic reactions at the MP2//6-31G(d) level of theory. In the same study,  $\Delta H_f^\circ = -614 \pm 7 \text{ kJ mol}^{-1}$  for CF<sub>2</sub>O and  $\Delta H_f^\circ = -381 \pm 2 \text{ kJ mol}^{-1}$  for CHFO were calculated, both close to the recommended values.<sup>7</sup>

### **CF<sub>3</sub>C(O)OH, trifluoroacetic acid**

Enthalpy value from review of Pedley.<sup>4</sup>

### **CF<sub>3</sub>OCO<sub>2</sub>**

An average of a result from an isodesmic reaction and an atomization energy, both calculated at the CBS-4 level of theory.<sup>3</sup>

### **CF<sub>3</sub>OOCF<sub>3</sub>**

A thermal decomposition study from 575 to 900 K led to a BDE(O-O) of  $47.5 \pm 0.5 \text{ kcal mol}^{-1}$ .<sup>5</sup> An MP2//6-31G(d,p) calculation utilizing isodesmic and isogyric reactions resulted in  $-343 \pm 3 \text{ kcal mol}^{-1}$ .<sup>6</sup> A CBS-QB3 calculation led to a BDE(O-O) of  $209.4 \text{ kJ mol}^{-1}$ , and thus an enthalpy of  $-1479 \text{ kJ mol}^{-1}$ .<sup>1</sup>

[Back to Table](#)

- iso-C<sub>3</sub>H<sub>7</sub>F** Enthalpies of reaction calculated at the MCG3//MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction and averaged. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support<sup>2</sup>  $\Delta_fH_{298}^o = -318.8 \pm 4.2 \text{ kJ mol}^{-1}$  estimated by Luo and Benson.<sup>3</sup>
- tert-C<sub>4</sub>H<sub>9</sub>F** Enthalpies of reaction calculated at the MCG3//MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction and averaged. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support.<sup>2</sup>  $\Delta_fH_{298}^o = -363.6 \pm 4.2 \text{ kJ mol}^{-1}$  estimated by Luo and Benson.<sup>3</sup>

**CF<sub>3</sub>C(O)OCH<sub>3</sub>**

The free energy of formation of methyl trifluoroacetate in solution was determined by measuring the equilibrium constant for the reaction of trifluoroacetic acid with methanol. The solubility was estimated from a linear free-energy relationship and the vapor pressure estimated from the boiling point, leading to a value of the free energy of formation in the gas phase. Combining this with the estimate of the standard entropy, also listed, leads to the cited value.<sup>1</sup> A density-functional calculation at the MPWB1K//6-31+G(d,p) level with two isodesmic reactions, led to  $\Delta_fH_{298}^o = -1020 \text{ kJ mol}^{-1}$ .<sup>4</sup>

**Note 29:** Inorganic compounds containing Cl

[Back to Table](#)

- Cl** Enthalpy value is from the optimization of Ruscic et al.<sup>20</sup> Entropy is a CODATA Key Value<sup>4</sup> as was the previous enthalpy value of  $\Delta_fH_{298}^o = 121.301 \pm 0.008 \text{ kJ mol}^{-1}$ .
- Cl<sub>2</sub>** CODATA Key Value<sup>4</sup>
- HCl** CODATA Key Value.<sup>4</sup> The active thermochemical tables optimization gives an enthalpy value of  $-92.1763 \pm 0.0063 \text{ kJ mol}^{-1}$ .<sup>20</sup> The most recent NIST-JANAF review gives an enthalpy of  $-92.31 \pm 0.10 \text{ kJ mol}^{-1}$  and an entropy of  $186.901 \pm 0.005 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>21</sup>
- ClO** Both JANAF<sup>3</sup> and Gurvich et al.<sup>9</sup> use the dissociation energy from Coxan and Ramsay<sup>5</sup> of  $265.380 \pm 0.036 \text{ kJ mol}^{-1}$ . The present recommendation is a recalculation using reference values from this Table. The entropy is a statistical mechanical calculation<sup>1</sup> using data from JANAF. The previous value of  $101.63 \pm 0.1 \text{ kJ mol}^{-1}$  was from the JANAF recommendation.<sup>3</sup> A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of  $24.8 \text{ kcal mol}^{-1}$  at both 0 K and at 298 K.<sup>16</sup> Another CCSD(T) calculation of the dissociation energy, both directly and thorough a negative ion thermochemical cycle, led to enthalpy values of  $\Delta_fH_0^o = 24.1 \pm 0.3$  and  $\Delta_fH_{298}^o = 24.1 \pm 0.3$

and  $24.2 \pm 0.3$  kcal mol<sup>-1</sup>.<sup>18</sup> Atomization energy was calculated using the Wn family of computational methods. A slight increase in the atomization energy was found going from W2.2 to W4.4. These results led to  $\Delta_f H_{298}^o = 101.2 \pm 0.4$  kJ mol<sup>-1</sup> and a 0 K value only 0.04 kJ mol<sup>-1</sup> higher.<sup>12</sup>

<b>CIOO</b>	Enthalpy and entropy values are from an analysis of equilibrium constant measurements (see Table 3-1, Note 11). More recent measurements over the temperature range 212–245 K <sup>23</sup> support these values. Previous enthalpy value of $98 \pm 4$ kJ mol <sup>-1</sup> and entropy value of $269.32 \pm 0.5$ J K <sup>-1</sup> mol <sup>-1</sup> from JANAF. Enthalpy for the reaction HOOC + FOO → HOOF + CIOO at the CCSD(T)/CBS(Q5) level of theory, adjusted for the Table value for FOO, leads to $\Delta_f H_{298}^o = 103.9 \pm 6$ kJ mol <sup>-1</sup> and $\Delta_f H_0^o = 104.7 \pm 6$ kJ mol <sup>-1</sup> . <sup>8</sup> Atomization energy was calculated using the Wn family of computational methods. Significant increases in the atomization energy were found going from W2.2 to W4.4. These results led to $\Delta_f H_{298}^o = 101.7 \pm 0.7$ kJ mol <sup>-1</sup> and $\Delta_f H_0^o = 103.3 \pm 0.7$ kJ mol <sup>-1</sup> . <sup>12</sup>
<b>CIOOH</b>	Isodesmic reaction calculations done at MP2, CCSD, and CCSD(T) level with ANO basis sets to determine enthalpy of formation. <sup>14</sup>
<b>OCIO</b>	Near-threshold fragmentation studies led to a dissociation energy to O + ClO of $247.3 \pm 0.5$ kJ mol <sup>-1</sup> . <sup>6</sup> This leads to an enthalpy of formation at 0 K of $100.6 \pm 0.6$ kJ mol <sup>-1</sup> . A computational study gives, at 0 K, $102.2 \pm 6.5$ kJ mol <sup>-1</sup> . <sup>13</sup> Previous 298 K enthalpy of formation, $94.6 \pm 1.2$ , derived from equilibrium constant for ClO + ClO ↔ Cl + OCIO. <sup>17</sup> Entropy and enthalpy function are from JANAF. <sup>3</sup> A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of 24.5 kcal mol <sup>-1</sup> at 0 K and 23.9 at 298 K. <sup>16</sup> An atomization energy calculated at the W4 level of theory led to $\Delta_f H_{298}^o = 99.0 \pm 0.7$ kJ mol <sup>-1</sup> and $\Delta_f H_0^o = 101.5 \pm 0.7$ kJ mol <sup>-1</sup> . <sup>12</sup>
<b>ClO<sub>3</sub></b>	A calculation of the isodesmic reaction ClO <sub>3</sub> + ClO → 2OCIO at the W4.2 level of theory provided the selected enthalpy values. <sup>12</sup> The previous values, $\Delta_f H_{298}^o = 194 \pm 12$ kJ mol <sup>-1</sup> and $\Delta_f H_0^o = 200 \pm 12$ kJ mol <sup>-1</sup> were the JANAF recommendations, which were based on limited kinetic and theoretical studies. <sup>3</sup> A more recent density functional/G3 calculation led to a 298 K enthalpy of 43.1 kcal mol <sup>-1</sup> (= 180.3 kJ mol <sup>-1</sup> ). <sup>22</sup>
<b>CICIO</b>	A CCSD(T), extrapolated to the complete basis set limit, for the atomization energy leads to the recommended enthalpy of formation and a value of 32.2 kcal mol <sup>-1</sup> at 0 K. For the <sup>1</sup> A' state. $\Delta_f H_{298}^o = 52.4 \pm 1$ kcal mol <sup>-1</sup> for the <sup>3</sup> A" state. <sup>16</sup> The previous recommendation, $90 \pm 30$ kJ mol <sup>-1</sup> , from the JANAF evaluation, <sup>3</sup> was based on an interpretation of the infrared spectrum and suggested that ClCIO was less stable than ClOCl by ~9 kJ mol <sup>-1</sup> . Several computational studies cited in the JANAF review indicated that the stability difference was considerably greater, typically about 60 kJ mol <sup>-1</sup> . The present recommendation leads to a stability difference of 52 kJ mol <sup>-1</sup> . Entropy and enthalpy difference calculated by a statistical mechanical calculation using vibrational frequencies from the WebBook and PM3 rotational moments. <sup>1</sup>
<b>ClOCl</b>	Enthalpy value based on experimental reports on the equilibrium constant for the reaction H <sub>2</sub> O + Cl <sub>2</sub> O ↔ 2HOCl and the recommended enthalpy of formation for HOCl. <sup>10</sup> Gurvich et al. recommended an enthalpy of formation at 298 K of $79 \pm 10$ kJ mol <sup>-1</sup> . <sup>9</sup> A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of 19.3 kcal mol <sup>-1</sup> at 0 K and 18.9 at 298 K. <sup>16</sup>
<b>CIOOC</b>	Selected enthalpy value derived from a third-law calculation on the equilibrium constant for the dimerization reaction, ClO + ClO ↔ ClOOCl, presented in Table 3-1, note 20. Entropy value calculation is also discussed in Table 3-1. Previous Table value of $\Delta_f H_{298}^o$ , $127.6 \pm 2.9$ kJ mol <sup>-1</sup> , was from the equilibrium constant of Nickolasen, et al. <sup>17</sup> and the entropy was the JANAF recommendation. <sup>3</sup> A study of the fragmentation threshold of ClO <sup>+</sup> from the photoionization of ClOOCl yielded a 0 K enthalpy of $134.07 \pm 2.8$ kJ mol <sup>-1</sup> and a 298 K value of $130.87 \pm 2.8$ kJ mol <sup>-1</sup> . <sup>19</sup> A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of 32.9 kcal mol <sup>-1</sup> at 0 K and 31.6 at 298 K. <sup>16</sup> A calculation using the isodesmic reactions ClOOCl + H <sub>2</sub> O → H <sub>2</sub> O <sub>2</sub> + Cl <sub>2</sub> O and

	CLOOCl + 2HOCl → H <sub>2</sub> O <sub>2</sub> + 2Cl <sub>2</sub> O at the W4.2 level of theory leads to $\Delta_fH_{298}^o = 131.8 \pm 1.3$ kJ mol <sup>-1</sup> and $\Delta_fH_0^o = 135.1 \pm 1.3$ kJ mol <sup>-1</sup> . <sup>12</sup>
<b>ClClO<sub>2</sub></b>	Derived from a CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy. <sup>16</sup> See Table 3-1, note 21 for a more complete discussion. The previous value, 154.2 kJ mol <sup>-1</sup> (36.9 kcal mol <sup>-1</sup> ), was calculated at Gaussian-2 level of theory. <sup>15</sup> Entropy from JANAF evaluation. <sup>3</sup> The same value resulted from a statistical mechanical calculation.
<b>ClOCIO</b>	Derived from a CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy <sup>16</sup> combined with G2 composite calculations. <sup>25</sup> See Table 3-1, note 20b for a more complete discussion. The previous value, 175.5 kJ mol <sup>-1</sup> (41.9 kcal mol <sup>-1</sup> ), was calculated at Gaussian-2 level of theory <sup>15</sup> and the previous entropy (309±2 kJ mol <sup>-1</sup> ) was from the JANAF evaluation. <sup>3</sup>
<b>Cl<sub>2</sub>O<sub>3</sub></b>	Selected enthalpy and entropy values derived from a third-law calculation on the equilibrium constant for the reaction, ClO + OCLO ↔ Cl <sub>2</sub> O <sub>3</sub> , presented in Table 3-1, note 15. Previous values in Table, $\Delta_fH = 35.8 \pm 1.5$ kcal mol <sup>-1</sup> and $\Delta S = 94 \pm 5$ cal K <sup>-1</sup> mol <sup>-1</sup> , were taken from a single study. <sup>2</sup> The most stable structure among the Cl <sub>2</sub> O <sub>3</sub> isomers is calculated to be ClOCl(O)O. <sup>26</sup> A density functional/G3 calculation led to a 298 K enthalpy of 31.7 kcal mol <sup>-1</sup> . <sup>22</sup>
<b>HOCl</b>	Enthalpy value from an evaluation of the experimental data. <sup>10</sup> Entropy and the enthalpy difference from JANAF evaluation. <sup>3</sup> An enthalpy value of $-18.1 \pm 0.3$ kcal mol <sup>-1</sup> has been calculated by coupled-cluster theory with correlation consistent basis sets and corrections for core-valence, relativistic, and anharmonic effects. <sup>7</sup> A calculation of the isodesmic reaction HOF + OH → FO + H <sub>2</sub> O at the W4.2 level of theory leads to $\Delta_fH_{298}^o = -76.1 \pm 0.6$ kJ mol <sup>-1</sup> and $\Delta_fH_0^o = -73.4 \pm 0.6$ kJ mol <sup>-1</sup> . <sup>12</sup> A re-evaluation of the spectroscopic results, along with a newer value for the OH enthalpy, has led to a recommended value of $\Delta_fH_0^o = -73.99 \pm 0.12$ kJ mol <sup>-1</sup> . <sup>11</sup>
<b>HOClO</b>	A calculation of the isodesmic reaction HOClO + ClO → HOCl + OCLO at the W4lite level of theory provided the selected enthalpy values. <sup>12</sup>
<b>HOClO<sub>2</sub></b>	The total atomization energy was calculated at the W2.2 level of theory and then corrected to provide an estimated W4lite value, leading to the selected enthalpy values. <sup>12</sup>
<b>HOClO<sub>3</sub></b>	The total atomization energy was calculated at the W2.2 level of theory, leading to the selected enthalpy values. <sup>12</sup>
<b>ClF</b>	Taken from review of Gurvich et al. <sup>9</sup> The JANAF Tables give $\Delta_fH_0^o = -50.2 \pm 0.4$ kJ mol <sup>-1</sup> , $\Delta_fH_{298}^o = -50.3 \pm 0.4$ kJ mol <sup>-1</sup> , and $S^o = 217.938$ J mol <sup>-1</sup> . <sup>3</sup> A study in which the total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections, gave $\Delta_fH_{298}^o = -54.8$ kJ mol <sup>-1</sup> . <sup>24</sup>
<b>ClOF</b>	The total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections. <sup>24</sup>
<b>ClO<sub>2</sub>F</b>	The total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections. <sup>24</sup>

[Back to Table](#)

<b>ClNO</b>	Taken from review of Gurvich et al. <sup>4</sup> The JANAF Tables give $\Delta_f H_0^\circ = 53.6 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 51.7 \text{ kJ mol}^{-1}$ , and $S^\circ = 261.680 \text{ J mol}^{-1}$ . <sup>2</sup>
<b>ClNO<sub>2</sub></b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>8</sup> The previous value, $\Delta_f H_{298}^\circ = 52.7 \pm 0.5 \text{ kJ mol}^{-1}$ , was taken from review of Gurvich et al. <sup>4</sup> The JANAF Tables give $\Delta_f H_0^\circ = 17.5 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 12.1 \text{ kJ mol}^{-1}$ , and $S^\circ = 272.187 \text{ J mol}^{-1}$ . <sup>2</sup>
<b>cis-ClONO</b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>8</sup> The previous value, $\Delta_f H_{298}^\circ = 64.6 \text{ kJ mol}^{-1}$ , was predicted based on isodesmic reactions at the CCSD(T) level of theory. <sup>5</sup>
<b>trans-ClONO</b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>8</sup> The previous value, $\Delta_f H_{298}^\circ = 75.3 \text{ kJ mol}^{-1}$ , was predicted based on isodesmic reactions at the CCSD(T) level of theory. <sup>5</sup>
<b>cis, perp-ClO<sub>2</sub>NO</b>	Enthalpy calculated at MP2 level of theory using basis sets ranging from 6-31G(d) to 6-311G(2df,2p). <sup>7</sup> A G3//B3LYP study gave enthalpies at 0 K and 298 K of 32.5 and 31.5 kcal mol <sup>-1</sup> , respectively. <sup>6</sup>
<b>trans, perp-ClO<sub>2</sub>NO</b>	Enthalpy calculated at MP2 level of theory using basis sets ranging from 6-31G(d) to 6-311G(2df,2p). <sup>7</sup> A G3//B3LYP study gave enthalpies at 0 K and 298 K of 34.4 and 33.2 kcal mol <sup>-1</sup> , respectively. <sup>6</sup>
<b>ClONO<sub>2</sub></b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>8</sup> The previous value, $\Delta_f H_{298}^\circ = 22.9 \pm 2.0 \text{ kJ mol}^{-1}$ , was derived from a study of the thermal dissociation of ClONO <sub>2</sub> . <sup>1</sup> Enthalpy values obtained from the atomization energy obtained using the G3//B3LYP level of theory are $\Delta_f H_0^\circ = 7.0 \text{ kcal mol}^{-1}$ and $\Delta_f H_{298}^\circ = 5.5 \text{ kcal mol}^{-1}$ . <sup>6</sup>
<b>cis,perp-ClOONO</b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>8</sup> The previous value, $\Delta_f H_{298}^\circ = 132 \text{ kJ mol}^{-1}$ , was obtained from the atomization energy obtained using the G3//B3LYP level of theory. <sup>6</sup>
<b>trans, perp-CIOONO</b>	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. <sup>8</sup> The previous value, $\Delta_f H_{298}^\circ = 132 \text{ kJ mol}^{-1}$ , was obtained from the atomization energy obtained using the G3//B3LYP level of theory. <sup>6</sup>
<b>trans, perp-OCIONO</b>	

Value obtained from the atomization energy obtained using the G3//B3LYP level of theory.<sup>6</sup>

**O<sub>2</sub>CIONO<sub>2</sub>** Based on a study of the recombination of OCIO and NO<sub>3</sub>, leading to a bond strength of 18±3 kcal mol<sup>-1</sup>.<sup>3</sup>

**NH<sub>2</sub>Cl, NHCl<sub>2</sub>, NCl<sub>3</sub>, chloramines**

Geometries were optimized at the (AE)-CCSD(T)/AVQZ level of theory and zero-point energies computed at the B2PLYPD/AVQZ level. For the electronic energies, a calculational protocol termed TA14 was adapted from the W3, W4, and FPD protocols. Enthalpies of formation were determined from the total atomization energies.<sup>9</sup>

**Note 31: Compounds containing one C and one or more Cl and H**

[Back to Table](#)

**CCl** Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing a number of individual CCSD(T) energies with the basis set limited HF energy, along with other contributions.<sup>1</sup>

**CHCl** Calculated for the X<sup>1</sup>A' state. The triplet-singlet energy gap is estimated to be 2170±40 cm<sup>-1</sup>. Enthalpy determined by calculating the enthalpy of the reaction CH<sub>2</sub> + HCl → HCCl + H<sub>2</sub>. Calculations involved the focal-point approach, based on methods up to CCSDTQ and basis sets ranging from aug-cc-pVDZ to aug-cc-pV6Z, extrapolated to the complete basis set limit.<sup>12</sup> Enthalpy obtained using the computed enthalpy of a reaction of the type: CH<sub>2</sub>(<sup>1</sup>A<sub>1</sub>) + CH<sub>3</sub>X + CH<sub>3</sub>Y ↔ CXY(<sup>1</sup>A<sub>1</sub>) + 2CH<sub>4</sub> results in  $\Delta_f H_{298}^o = 320$  kJ mol<sup>-1</sup> at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.<sup>9</sup> Previous recommendation was based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations.<sup>7</sup> Entropy values from Gurvich et al. review.<sup>2</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to  $\Delta_f H_0^o = 320.1 \pm 2.3$  kJ mol<sup>-1</sup>,  $\Delta_f H_{298}^o = 320.3 \pm 2.3$  kJ mol<sup>-1</sup>, and  $S = 234.6 \pm 1.5$  J K<sup>-1</sup> mol<sup>-1</sup>.<sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.

**CH<sub>2</sub>Cl** Measured rate constant for the reaction of the radical with HBr, combined with previous measurements on the reverse reaction, with thermodynamic values obtained through a second-

law analysis.<sup>11</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of  $117.0 \pm 4.1 \text{ kJ mol}^{-1}$ .<sup>10</sup> A dissociative photoionization study of CH<sub>2</sub>ClBr results in an enthalpy of  $110.7 \text{ kJ mol}^{-1}$ .<sup>5</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to  $\Delta_f H_0^\circ = 119.4 \pm 2.7 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = 116.0 \pm 2.7 \text{ kJ mol}^{-1}$ , and  $S = 236.3 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.

<b>CH<sub>3</sub>Cl</b>	Enthalpy from Manion evaluation. <sup>6</sup> Entropy from Thermodynamics Research Center evaluation. <sup>8</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -74.3 \pm 3.1 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -82.6 \pm 3.1 \text{ kJ mol}^{-1}$ , and $S = 234.0 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CCl<sub>2</sub></b>	Calculated for the X <sup>1</sup> A' state. The triplet-singlet energy gap is estimated to be $7045 \pm 60 \text{ cm}^{-1}$ . Enthalpy determined by calculating the enthalpy of the reaction $\text{CH}_2 + 2\text{HCl} \rightarrow \text{CCl}_2 + 2\text{H}_2$ . Calculations involved the focal-point approach, based on methods up to CCSDTQ and basis sets ranging from aug-cc-pVDZ to aug-cc-pV6Z, extrapolated to the complete basis set limit. <sup>12</sup> Enthalpy obtained using the computed enthalpy of a reaction of the type: $\text{CH}_2(^1\text{A}_1) + \text{CH}_3\text{X} + \text{CH}_3\text{Y} \rightarrow \text{CXY}(^1\text{A}_1) + 2\text{CH}_4$ results in $\Delta_f H_{298}^\circ = 230 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. <sup>9</sup> Previous recommendation ( $55.0 \pm 2.0 \text{ kcal mol}^{-1}$ ) based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations. <sup>7</sup> Entropy values from Gurvich et al. review. <sup>2</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 229.0 \pm 1.9 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 230.1 \pm 1.9 \text{ kJ mol}^{-1}$ , and $S = 264.5 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CHCl<sub>2</sub></b>	Measured rate constant for the reaction of the radical with HBr, combined with previous measurements on the reverse reaction, with thermodynamic values obtained through a second-law analysis. <sup>11</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $91.1 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>10</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 91.2 \pm 4.8 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 88.8 \pm 5.8 \text{ kJ mol}^{-1}$ , and $S = 280.7 \pm 6.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CH<sub>2</sub>Cl<sub>2</sub></b>	Enthalpy from Manion evaluation. <sup>6</sup> Entropy from Thermodynamics Research Center evaluation. <sup>8</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -86.5 \pm 4.2 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -93.7 \pm 4.2 \text{ kJ mol}^{-1}$ , and $S = 269.7 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CCl<sub>3</sub></b>	A third-law determination based on the reaction $\text{CCl}_3 + \text{Br}_2 \leftrightarrow \text{CCl}_3\text{Br} + \text{Br}$ , re-evaluating the kinetics of the reverse reaction and using spectroscopic data to calculate the entropy. <sup>4</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $72.2 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>10</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 73.7 \pm 4.9 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = 73.1 \pm 4.9 \text{ kJ mol}^{-1}$ , and $S = 301.3 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CHCl<sub>3</sub></b>	Enthalpy from Manion evaluation. <sup>6</sup> Entropy from Thermodynamics Research Center evaluation. <sup>8</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 94.6 \pm 5.3 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -99.7 \pm 5.3 \text{ kJ mol}^{-1}$ , and $S =$

$294.8 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table.

#### CCl<sub>4</sub>

Enthalpy from Manion evaluation.<sup>6</sup> Entropy from Thermodynamics Research Center evaluation.<sup>8</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to  $\Delta_f H_0^\circ = -88.8 \pm 6.4 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = -91.0 \pm 6.4 \text{ kJ mol}^{-1}$ , and  $S = 308.6 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>1</sup> The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with *ab initio* calculations of isodesmic and exchange reactions into a thermochemical network, leading to  $\Delta_f H_0^\circ = -94.0 \pm 3.2 \text{ kJ mol}^{-1}$ .<sup>3</sup>

**Note 32:** Compounds containing one C and one or more Cl, H, and O      [Back to Table](#)

#### CClH<sub>2</sub>O and CClH<sub>2</sub>OH

The enthalpies of formation based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.<sup>11</sup>

#### CClO

Second- and third-law analyses of the equilibration kinetics for the reaction Cl + CO  $\leftrightarrow$  ClCO led to  $\Delta_r H_{298}^\circ = -7.7 \pm 0.6 \text{ kcal mol}^{-1}$ ,  $\Delta_r H_0^\circ = -6.9 \pm 0.7 \text{ kcal mol}^{-1}$ , and  $\Delta_r S_{298}^\circ = -23.8 \pm 2.0 \text{ cal mol}^{-1} \text{ K}^{-1}$ .<sup>9</sup> See also Table 3-1, Note 12. (Previous enthalpy value had a sign error.) A shock-tube study of the thermal decomposition of COCl<sub>2</sub> led to a value of  $\Delta_r H_0^\circ = -6.3 \pm 1.0 \text{ kcal mol}^{-1}$ .<sup>7</sup> Entropy value cited derived by using standard statistical mechanic methods.<sup>9</sup>

<b>CHClO</b>	The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set. <sup>8</sup> The previous $\Delta_f H_{298}^{\circ} = -164 \pm 20 \text{ kJ mol}^{-1}$ was estimated in the Gurvich et al. review. <sup>3</sup> Entropy was based on spectroscopic studies. <sup>3</sup>
<b>CH<sub>2</sub>OCl</b>	Molecular properties determined at the MP2/6-31G(p,d), B3LYP/6-31G(d,p), and MP2/6-31G(d) level with single-point energy calculations at B3LYP/6-311+G(3df,2p) levels. Enthalpy based on four isodesmic reactions calculated at the CBS-Q//MP2/6-31(G(d,p) level. <sup>1</sup>
<b>CH<sub>3</sub>OCl</b>	Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels. Enthalpies determined using several working reactions. <sup>4</sup>
<b>CH<sub>2</sub>ClO<sub>2</sub></b>	Based on a re-analysis of previous equilibrium data on R + O <sub>2</sub> $\leftrightarrow$ RO <sub>2</sub> from the same laboratory. <sup>5</sup>
<b>CH<sub>2</sub>ClOOH</b>	Molecular geometries determined at the B3LYP/6-31G(d,p) level of theory and electronic energies obtained through single-point calculations at the CBSQ level. Enthalpy of formation determined using five reaction schemes, three of which were isodesmic. <sup>13</sup> A study in which geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)//B3LYP/6-311++G(d,p) level. <sup>6</sup> The dissociation energy into HO <sub>2</sub> and the alkyl radical was then evaluated and used, after thermal correction, to calculate $\Delta_f H_{298}^{\circ} = -174 \text{ kJ mol}^{-1}$ , after adjustment to the values for CH <sub>3</sub> and HO <sub>2</sub> from the present Table.
<b>CCl<sub>2</sub>O</b>	Taken from "The Chemical Thermodynamics of Organic Compounds". <sup>12</sup> Pedley review gives an enthalpy value of $-219.1 \pm 0.5 \text{ kJ mol}^{-1}$ . <sup>10</sup>
<b>CCl<sub>2</sub>HO and CCl<sub>2</sub>HOH</b>	The enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory. <sup>11</sup>
<b>CHCl<sub>2</sub>O<sub>2</sub></b>	Based on a re-analysis of previous equilibrium data on R + O <sub>2</sub> $\leftrightarrow$ RO <sub>2</sub> from the same laboratory. <sup>5</sup>
<b>CH<sub>2</sub>ClOCl</b>	Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels. Enthalpies determined using several working reactions. <sup>4</sup>
<b>CHCl<sub>2</sub>OOH</b>	Molecular geometries determined at the B3LYP/6-31G(d,p) level of theory and electronic energies obtained through single-point calculations at the CBSQ level. Enthalpy of formation determined using five reaction schemes, three of which were isodesmic. <sup>13</sup>
<b>CHCl<sub>2</sub>OCl</b>	Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels. Enthalpies determined using several working reactions. <sup>4</sup>
<b>CCl<sub>3</sub>O and CCl<sub>3</sub>OH</b>	Enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory. <sup>11</sup>
<b>CCl<sub>3</sub>O<sub>2</sub></b>	Based on a re-analysis of previous equilibrium data on R + O <sub>2</sub> $\leftrightarrow$ RO <sub>2</sub> from the same laboratory. <sup>5</sup>
<b>CCl<sub>3</sub>OOH</b>	Molecular geometries determined at the B3LYP/6-31G(d,p) level of theory and electronic energies obtained through single-point calculations at the CBSQ level. Enthalpy of formation determined using five reaction schemes, three of which were isodesmic. <sup>13</sup>
<b>CCl<sub>3</sub>OCl</b>	Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels.

[Back to Table](#)

<b>CHFCI</b>	Enthalpy derived from an analysis of thermochemical and kinetic data on the bromination of CH <sub>2</sub> FCl. <sup>12</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-63.8 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>11</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^o = -64.6 \pm 3.7 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^o = -67.8 \pm 4.7 \text{ kJ mol}^{-1}$ , and $S = 273.5 \pm 6.5 \text{ J K}^{-1} \text{ mol}^{-1}$ (used in the Table). <sup>3</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CH<sub>2</sub>FCI</b>	Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions. <sup>3</sup> Previous enthalpy from Pedley review <sup>7</sup> and entropy from Thermodynamics Research Center review. <sup>1</sup>
<b>CFCI</b>	Recommendation based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations. <sup>8</sup> Enthalpy obtained using the computed enthalpy of a reaction of the type: CH <sub>2</sub> ( <sup>1</sup> A <sub>1</sub> ) + CH <sub>3</sub> X + CH <sub>3</sub> Y → CXY( <sup>1</sup> A <sub>1</sub> ) + 2CH <sub>4</sub> results in $\Delta_f H_{298}^o = 29.4 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-

311G(d,p) level of theory. Calculations also done at the G2 level.<sup>10</sup> Entropy values from Gurvich et al. review.<sup>4</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to  $\Delta_f H_0^\circ = 32.2 \pm 2.3 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = 32.0 \pm 2.3 \text{ kJ mol}^{-1}$ , and  $S = 258.9 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>3</sup> The enthalpy difference was used to calculate the 0 K value in the Table.

<b>CF<sub>2</sub>Cl</b>	Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions. <sup>3</sup> A photobromination study leads to $D(\text{CClF}_2\text{-H}) = 100.7 \pm 2 \text{ kcal mol}^{-1}$ . <sup>6</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-274.7 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>11</sup>
<b>CFCl<sub>2</sub></b>	Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions. <sup>3</sup> An enthalpy of $-89.1 \pm 10 \text{ kJ mol}^{-1}$ was derived from an analysis of thermochemical and kinetic data on the bromination of CH <sub>2</sub> FCl. <sup>12</sup> A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-94.3 \pm 4.1 \text{ kJ mol}^{-1}$ . <sup>11</sup>
<b>CHFCl<sub>2</sub></b>	Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions. <sup>3</sup> Previous enthalpy value, from the Thermodynamics Research Center review, <sup>1</sup> was estimated.
<b>CHF<sub>2</sub>Cl</b>	Enthalpy from Pedley <sup>7</sup> review and entropy from Thermodynamics Research Center review. <sup>1</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -475.7 \pm 3.1 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -482.2 \pm 3.1 \text{ kJ mol}^{-1}$ , and $S = 280.5 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>3</sup> The enthalpy difference was used to calculate the 0 K value in the Table.
<b>CFCl<sub>3</sub></b>	Enthalpy based on equilibrium measurements for the reaction $\text{CClF}_3 + 2\text{CCl}_4 \leftrightarrow 3\text{CCl}_3\text{F}$ leading to a heat of reaction of 10.59 kcal mol <sup>-1</sup> , changed to reflect present enthalpy values. <sup>2</sup> Pedley review gives an enthalpy value of $-268.3 \pm 8.4 \text{ kJ mol}^{-1}$ . <sup>7</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -286.0 \pm 5.3 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -282.7 \pm 5.3 \text{ kJ mol}^{-1}$ , and $S = 308.6 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>3</sup> The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with <i>ab initio</i> calculations of isodesmic and exchange reactions into a thermochemical network, leading to $\Delta_f H_0^\circ = -285.2 \pm 3.2 \text{ kJ mol}^{-1}$ . <sup>5</sup>
<b>CF<sub>2</sub>Cl<sub>2</sub></b>	Enthalpy based on equilibrium measurements for the reaction $2\text{CClF}_3 + \text{CCl}_4 \leftrightarrow 3\text{CCl}_2\text{F}_2$ leading to a heat of reaction of 7.59 kcal mol <sup>-1</sup> , changed to reflect present enthalpy values. <sup>2</sup> Pedley review gives an enthalpy value of $-477.4 \pm 7.2 \text{ kJ mol}^{-1}$ . <sup>7</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -487.9 \pm 4.2 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^\circ = -492.1 \pm 4.2 \text{ kJ mol}^{-1}$ , and $S = 300.2 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ . <sup>3</sup> The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with <i>ab initio</i> calculations of isodesmic and exchange reactions into a thermochemical network, leading to $\Delta_f H_0^\circ = -487.8 \pm 3.4 \text{ kJ mol}^{-1}$ . <sup>5</sup>
<b>CF<sub>3</sub>Cl</b>	Enthalpy from a simultaneous solution of a thermochemical network for the CF <sub>3</sub> X species, where X = nil, H, Cl, Br, I, CF <sub>3</sub> , CN. <sup>9</sup> Entropy from recommendation of the Thermodynamics Research Center. <sup>2</sup> A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation

using the HEAT protocols, led to  $\Delta_f H_0^\circ = -703.4 \pm 3.1 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = -708.6 \pm 3.1 \text{ kJ mol}^{-1}$ , and  $S = 284.7 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>3</sup> The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with *ab initio* calculations of isodesmic and exchange reactions into a thermochemical network, leading to  $\Delta_f H_0^\circ = -702.1 \pm 3.5 \text{ kJ mol}^{-1}$ .<sup>5</sup>

**Note 34:** Compounds containing one C and one or more Cl, F, and O      [Back to Table](#)

**CFCIO** The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.<sup>7</sup> Previous enthalpy value of  $-429 \pm 20 \text{ kJ mol}^{-1}$  estimated in the Gurvich et al. review.<sup>5</sup> The recommended entropy is taken from the Gurvich et al. review.

**CF<sub>3</sub>OCl** Based on photoionization study. Enthalpy presented as lower limit.<sup>1</sup> A G2 calculation led to an enthalpy of  $-768.3 \text{ kJ mol}^{-1}$ .<sup>4</sup>

**CCl<sub>3</sub>OF** Derived from a G2 calculation of the total energy of formation from the gas-phase elements.<sup>3</sup>

**cis- and trans-FC(O)OCI**

Enthalpy computed at the G3//B3LYP/6-311++G(3df,3pd) level of theory with both atomization energies and isodesmic reactions.<sup>2</sup>

**CHClFOOH and CCl<sub>2</sub>FOOH**

Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)/B3LYP/6-311++G(d,p) level. The dissociation energy into  $\text{HO}_2$  and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.<sup>6</sup> This was adjusted to the radical values from the present Table.

[Back to Table](#)

### **ClCH<sub>2</sub>CH<sub>2</sub>OH**

The enthalpy of formation of the liquid was determined by using rotating-bomb combustion calorimetry to be  $\Delta_fH_{298}^{\circ}(l) = -315.5 \pm 0.7$  kJ mol<sup>-1</sup>. The molar enthalpy of vaporization was then determined by use of Calvert-drop microcalorimetry as  $\Delta_{\text{vap}}H_{298}^{\circ} = 48.32 \pm 0.37$  kJ mol<sup>-1</sup>.<sup>1</sup>

### **CH<sub>3</sub>CHClO<sub>2</sub>**

Based on a re-analysis of previous equilibrium data on  $R + O_2 \leftrightarrow RO_2$  from the same laboratory.<sup>4</sup>

### **CH<sub>3</sub>C(O)Cl, acetyl chloride**

Enthalpy from review of Pedley.<sup>6</sup>

### **CH<sub>2</sub>ClC(O)OH**

Review of the literature.<sup>2</sup> Pedley review gives an enthalpy value of  $-435.2 \pm 9.3$  kJ mol<sup>-1</sup>.<sup>6</sup>

### **CH<sub>2</sub>ClCOOH**

Geometries and frequencies calculated at the B3LYP/6-31G(d,p) level of theory. Enthalpy calculated from three isodesmic reactions at the CBSQ//B3LYP/6-31(Gd,p) level and corrected for mixing of rotational conformers.<sup>7</sup>

#### **CH<sub>3</sub>CHClOOH**

Geometric parameters calculated at the RHF/6-31G\* and MP2/6-31G\* levels of theory, and the entropy obtained using the rigid-rotor/harmonic-oscillator approximation. Enthalpy calculated using the isodesmic reaction CH<sub>3</sub>OOH + C<sub>2</sub>H<sub>5</sub>Cl  $\leftrightarrow$  CH<sub>3</sub>CHClOOH + CH<sub>4</sub>, adjusted with reference values from the present Table.<sup>5</sup>

#### **CH<sub>3</sub>CCl<sub>2</sub>OOH**

Geometric parameters calculated at the RHF/6-31G\* and MP2/6-31G\* levels of theory, and the entropy obtained using the rigid-rotor/harmonic-oscillator approximation. Enthalpy calculated using the isodesmic reaction CH<sub>3</sub>OOH + 1,1-C<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub>  $\leftrightarrow$  CH<sub>3</sub>CCl<sub>2</sub>OOH + CH<sub>4</sub>, adjusted with reference values from the present Table.<sup>5</sup>

#### **CH<sub>2</sub>ClC(O)OCl, chloroacetyl chloride**

Enthalpy value taken from review of Pedley.<sup>6</sup>

#### **Cl(O)CC(O)Cl, ethanedioyl dichloride (oxalyl chloride)**

Enthalpy value taken from review of Pedley.<sup>6</sup>

#### **CHCl<sub>2</sub>C(O)Cl, dichloroacetyl chloride**

Enthalpy value taken from review of Pedley.<sup>6</sup>

#### **CCl<sub>3</sub>CH<sub>2</sub>OOH**

Geometries and frequencies calculated at the B3LYP/6-31G(d,p) level of theory. Enthalpy calculated from three isodesmic reactions at the CBSQ//B3LYP/6-31(Gd,p) level and corrected for mixing of rotational conformers.<sup>7</sup>

#### **CCl<sub>3</sub>CO**

Enthalpy is an average of values obtained at the CBS-4//HF/3-21G\* and G2(MP2(full)//MP2(full)/6-31G(d) levels of theory, using both atomization energies and formation from molecular species. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.<sup>8</sup>

#### **CCl<sub>3</sub>C(O)H**

Thermodynamic properties calculated at the G2(MP2(full)//MP2(full)/6-31G(d) level of theory. Enthalpy from atomization energy and entropy calculated treating internal rotations as harmonic oscillators. Similar values obtained at the CBS-4//HF/3021G\* level.<sup>8</sup>

#### **CCl<sub>3</sub>C(O)Cl, trichloroacetyl chloride**

Enthalpy from review of Pedley.<sup>6</sup>

#### **CH<sub>3</sub>CCl<sub>2</sub>O<sub>2</sub>**

Based on the equilibrium study using laser photolysis/PI mass spectrometry,<sup>3</sup> adjusted by using the enthalpy for CH<sub>3</sub>CCl<sub>2</sub> cited in this Table.

#### **CHCl<sub>2</sub>CH<sub>2</sub>OOH**

Geometries and frequencies calculated at the B3LYP/6-31G(d,p) level of theory. Enthalpy calculated from three isodesmic reactions at the CBSQ//B3LYP/6-31(Gd,p) level and corrected for mixing of rotational conformers.<sup>7</sup>

**Note 39:** *Inorganic compounds containing Br*

[Back to Table](#)

**Br** CODATA Key Value.<sup>2</sup>

**Br<sub>2</sub>(g)** CODATA Key Value.<sup>2</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^0 = 33.1 \pm 4 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = 47.7 \pm 4 \text{ kJ mol}^{-1}$ .<sup>5</sup>

**HBr** CODATA Key Value.<sup>2</sup> The most recent NIST-JANAF review gives an enthalpy of  $-36.29 \pm 0.16 \text{ kJ mol}^{-1}$  and an entropy of  $198.699 \pm 0.005 \text{ J K}^{-1} \text{ mol}^{-1}$ .<sup>16</sup>

**BrO** Enthalpy derived from a photodissociation dynamics study using velocity map ion imaging.<sup>8</sup> Previous enthalpy value of  $30.2 \pm 0.4 \text{ kcal mol}^{-1}$  based on a Birge-Sponer extrapolation.<sup>18</sup> Entropy from the JANAF table for bromine oxides.<sup>1</sup> A CCSD(T) calculation of the dissociation energy, both directly and thorough a negative ion thermochemical cycle, led to enthalpy values of  $\Delta_f H_0^\circ = 31.4 \pm 0.4$  and  $\Delta_f H_{298}^0 = 29.6 \pm 0.4 \text{ kcal mol}^{-1}$ .<sup>15</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^0 = 128 \pm 6 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = 136 \pm 6 \text{ kJ mol}^{-1}$ .<sup>5</sup>

**OBrO** Enthalpy based on the photoionization appearance energy of BrO<sup>+</sup> from OBrO, recalculated using the Table enthalpy for BrO.<sup>9</sup> A newer computational study gives an enthalpy at 0 K of

$163.9 \pm 7.1$  kJ mol<sup>-1</sup>.<sup>10</sup> Entropy taken from the JANAF table for bromine oxides.<sup>1</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^o = 169.9 \pm 6$  kJ mol<sup>-1</sup> and  $\Delta_f H_0^o = 179.5 \pm 6$  kJ mol<sup>-1</sup>.<sup>5</sup>

- BrOO** Enthalpy for the reaction HOOBr + FOO → HOOF + BrOO at the CCSD(T)/CBS(Q5) level of theory, adjusted for the Table value for FOO, leads the cited enthalpy.<sup>5</sup> An estimate based on recombination rate constants for bromine atoms and subsequent calculations of interaction potentials, leads to a bond strength of about 1 kcal mol<sup>-1</sup> and  $\Delta_f H_{298}^o = 108 \pm 40$  kJ mol<sup>-1</sup> and  $\Delta_f H_0^o = 116 \pm 10$  kJ mol<sup>-1</sup>.<sup>1</sup> These results have been supported by other computational studies.<sup>14,17</sup> CCSD(T)/AREP calculations predict, however, that BrOO lies below OBrO by about 5 kcal mol<sup>-1</sup>, which appears to be inconsistent with these results.<sup>14</sup> Entropy value is taken from NIST-JANAF thermochemical tables for bromine oxides.<sup>1</sup>
- BrO<sub>3</sub>** Estimated values taken from the NIST-JANAF thermochemical tables for bromine oxides.<sup>1</sup>
- BrOBr** Enthalpy derived from a photoionization study. This value was accepted by the NIST-JANAF thermochemical tables for bromine oxides, which also discussed three related studies and recommended the entropy value.<sup>1</sup> A CCSD(T)/ANO4 result based on the isodesmic reaction  $2\text{HOBr} \rightarrow \text{H}_2\text{O} + \text{Br}_2\text{O}$ , adjusted for the present enthalpy values for the references, gives  $26.9 \pm 1.6$  kcal mol<sup>-1</sup>.<sup>11</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^o = 108.4 \pm 6$  kJ mol<sup>-1</sup> and  $\Delta_f H_0^o = 124.7 \pm 6$  kJ mol<sup>-1</sup>.<sup>5</sup>
- BrBrO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. Listed value is for the <sup>1</sup>A' state.  $\Delta_f H_{298}^o = 236.0 \pm 6$  kJ mol<sup>-1</sup> for the <sup>3</sup>A'' state and  $\Delta_f H_{298}^o = 251.5 \pm 6$  kJ mol<sup>-1</sup> for the <sup>3</sup>A' state.<sup>5</sup> Entropy from the NIST-JANAF thermochemical tables for bromine oxides, which estimated the enthalpy as  $168 \pm 20$  kJ mol<sup>-1</sup>.<sup>1</sup>
- BrOOBr** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.<sup>5</sup> Calculated enthalpy for the reaction  $\text{BrO} + \text{BrO} \rightarrow \text{BrOOBr}$ ,  $\Delta E = -16.93$  kcal mol<sup>-1</sup> by B3LYP/aug-cc-pVTZ method, leads to  $\Delta_f H_{298}^o = 42.1$  kcal mol<sup>-1</sup>.<sup>4</sup> The dominant product observed in the matrix isolation/infrared spectroscopy study was BrOBrO.
- BrOBrO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.<sup>5</sup> Calculated enthalpy for the reaction  $\text{BrO} + \text{BrO} \rightarrow \text{BrOBrO}$ ,  $\Delta E = -6.08$  kcal mol<sup>-1</sup> by B3LYP/aug-cc-pVTZ method, leads to  $\Delta_f H_{298}^o = 52.9$  kcal mol<sup>-1</sup>.<sup>4</sup> The dominant product observed in the matrix isolation/infrared spectroscopy study was BrOBrO.
- OBrBrO** Calculated enthalpy for the reaction  $\text{BrO} + \text{BrO} \rightarrow \text{OBrBrO}$ ,  $\Delta E = +13.44$  kcal mol<sup>-1</sup> by B3LYP/aug-cc-pVTZ method.<sup>4</sup> The dominant product observed in the matrix isolation/infrared spectroscopy study was BrOBrO.
- BrBrO<sub>2</sub>** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.<sup>5</sup>
- HOBr** Enthalpy value from an evaluation of the experimental data.<sup>6</sup> An enthalpy value of  $-15.3 \pm 0.6$  kcal mol<sup>-1</sup> has been calculated by coupled-cluster theory with correlation consistent basis sets and corrections for core-valence, relativistic, and anharmonic effects.<sup>3</sup> Entropy value calculated from the experimental structure and vibrational frequencies.<sup>13</sup> A re-evaluation of the photoionization results, along with a newer value for the OH enthalpy, led to a value of  $\Delta_f H_0^o = -47.7 \pm 1.8$  kJ mol<sup>-1</sup>.<sup>7</sup>
- BrOOH** CCSD(T) calculation with spdfg one-particle basis set, using isodesmic reaction and present values of reference enthalpies.<sup>12</sup>

### HOBrO and HBrO<sub>2</sub>

Isomerization energy calculated at CCSD(T)/ANO4 level of theory, corrected for zero-point energy and to 298 K. BrOOH energy from present table.<sup>12</sup>

[Back to Table](#)

<b>BrCl</b>	Review of the literature. <sup>2</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^o = 15.9 \pm 6$ kJ mol <sup>-1</sup> and $\Delta_f H_0^o = 23.4 \pm 6$ kJ mol <sup>-1</sup> . <sup>1</sup>
<b>ClOBr</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>1</sup> A CCSD(T)/ANO4 study, based on the isodesmic reaction $HOB + HOCl \rightarrow H_2O + ClOBr$ , adjusted for the present enthalpy values for the references, led to $\Delta_f H_{298}^o = 98 \pm 7$ kJ mol <sup>-1</sup> . <sup>3</sup>
<b>ClBrO</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. $\Delta_f H_{298}^o = 145.2 \pm 6$ kJ mol <sup>-1</sup> for the ${}^3A''$ state and $\Delta_f H_{298}^o = 252.7 \pm 6$ kJ mol <sup>-1</sup> for the ${}^3A'$ state. <sup>1</sup>
<b>BrClO</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. Listed enthalpy is for the ${}^1A'$ state. $\Delta_f H_{298}^o = 226.4 \pm 6$ kcal mol <sup>-1</sup> for the ${}^3A'$ state. <sup>1</sup>

**CIOOBr, BIOBrO, BrOCIO, ClBrO<sub>2</sub>, BrClO<sub>2</sub>**

### Note 44: Compounds containing one C and one or more Br

[Back to Table](#)

<b>CBr</b>	Enthalpy from a CCSD(T) calculation extrapolated to the CBS limit. <sup>2</sup> A calculation at the W2DK level of theory gave an enthalpy of $118.51 \text{ kcal mol}^{-1}$ . <sup>7</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.
<b>CHBr</b>	Enthalpy from a CCSD(T) calculation extrapolated to the CBS limit. <sup>2</sup> A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of $90.12 \text{ kcal mol}^{-1}$ . <sup>7</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations. Enthalpy obtained using the computed enthalpy of a reaction of the type: $\text{CH}_2(^1\text{A}_1) + \text{CH}_3\text{X} + \text{CH}_3\text{Y} \rightarrow \text{CXY}(^1\text{A}_1) + 2\text{CH}_4$ results in $\Delta_f H_{298}^{\circ} = 380 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD(6-311G(d,p)) level of theory. Calculations also done at the G2 level. <sup>10</sup>
<b>CH<sub>2</sub>Br</b>	Measured rate constant for the reaction of the radical with HBr, combined with previous measurements on the reverse reaction, with thermodynamic values obtained through a second-law analysis. <sup>11</sup> Recalculated from C-H bond strength of $427.2 \text{ kJ mol}^{-1}$ and enthalpy for CH <sub>3</sub> Br and H from this Table. Statistical thermodynamic methods also utilized. <i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of $166.6 \pm 3 \text{ kJ mol}^{-1}$ . <sup>6</sup>

<b>CH<sub>3</sub>Br</b>	Calculated from the dissociation of energy-selected CH <sub>3</sub> Br <sup>+</sup> and its adiabatic ionization energy. <sup>12</sup> Enthalpy from Gurvich et al. review is $-36.4 \pm 0.5 \text{ kJ mol}^{-1}$ . <sup>3</sup> Entropy taken from Ideal Gas Thermodynamic Properties, which gives an enthalpy of $-37.7 \pm 1.5 \text{ kJ mol}^{-1}$ . <sup>4</sup> Pedley review gives an enthalpy of $-35.4 \pm 1.1 \text{ kJ mol}^{-1}$ . <sup>9</sup>
<b>CBr<sub>2</sub></b>	Enthalpy from a CCSD(T) calculation extrapolated to the CBS limit. <sup>2</sup> Enthalpy obtained using the computed enthalpy of a reaction of the type: CH <sub>2</sub> ( <sup>1</sup> A <sub>1</sub> ) + CH <sub>3</sub> X + CH <sub>3</sub> Y → CXY( <sup>1</sup> A <sub>1</sub> ) + 2CH <sub>4</sub> results in $\Delta_f H_{298}^{\circ} = 339 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. <sup>10</sup> A calculation at the W2DK level of theory gave an enthalpy of 82.10 kcal mol <sup>-1</sup> . <sup>7</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.
<b>CHBr<sub>2</sub></b>	Enthalpy derived from an analysis of thermochemical and kinetic data on the bromination of CH <sub>2</sub> Cl. <sup>13</sup> <i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of $191.7 \pm 6 \text{ kJ mol}^{-1}$ . <sup>6</sup> A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 47.44 kcal mol <sup>-1</sup> . <sup>7</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.
<b>CH<sub>2</sub>Br<sub>2</sub></b>	Enthalpy taken from a dissociative photoionization study of a series of dihalomethanes, normalized using the experimental enthalpy of dichloromethane. <sup>5</sup> The reported value has been adjusted by $+0.4 \text{ kJ mol}^{-1}$ to agree with the present enthalpy for CH <sub>2</sub> Cl <sub>2</sub> . Previous value of $-11.1 \text{ kJ mol}^{-1}$ from Allen bond-energy scheme. <sup>1</sup> <i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of $4.3 \pm 6 \text{ kJ mol}^{-1}$ . <sup>6</sup> Entropy from evaluation of Gurvich et al. <sup>3</sup>
<b>CBr<sub>3</sub></b>	Enthalpy value from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. <sup>6</sup> A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 55.50 kcal mol <sup>-1</sup> . <sup>7</sup> This same study, using a DFT approach for geometry optimization and frequency calculations, reported an entropy value of 80.60 cal K <sup>-1</sup> . Gurvich et al. review has $235 \pm 25 \text{ kJ mol}^{-1}$ . Entropy from Gurvich et al. <sup>3</sup>
<b>CHBr<sub>3</sub></b>	Enthalpy of formation derived from the heat of combustion of the liquid of $545.1 \pm 3.3 \text{ kJ mol}^{-1}$ measured by bomb calorimetry. <sup>8</sup> An enthalpy value of $51.6 \pm 9 \text{ kJ mol}^{-1}$ was obtained from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. <sup>6</sup> A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 12.97 kcal mol <sup>-1</sup> . <sup>7</sup> This same study, using a DFT approach for geometry optimization and frequency calculations, reported an entropy value of 78.93 cal K <sup>-1</sup> . Previous value of 5.7 kcal mol <sup>-1</sup> from Allen bond-energy scheme. <sup>1</sup> Entropy from evaluation of Gurvich et al. <sup>3</sup> Pedley gives enthalpy as $23.8 \pm 4.5 \text{ kJ mol}^{-1}$ . <sup>9</sup>
<b>CBr<sub>4</sub></b>	Enthalpy from rotation-bomb calorimetry. <sup>1</sup> <i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of $110.6 \pm 12 \text{ kJ mol}^{-1}$ . <sup>6</sup> A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 28.49 kcal mol <sup>-1</sup> . <sup>7</sup> This same study, using a DFT approach for geometry optimization and frequency calculations, reported an entropy value of 85.61 cal K <sup>-1</sup> . Entropy from Gurvich et al. <sup>3</sup>

[Back to Table](#)

**C<sub>2</sub>Br** An *ab initio* calculation at the W2DK level of theory.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

**C<sub>2</sub>HBr, bromoacetylene**

Enthalpy from measurements of the photodissociation of bromoacetylene, leading to dissociation energy of 91.0±1.2 kcal mol<sup>-1</sup>.<sup>8</sup>  $\Delta_f H_0^\circ = 71.3 \pm 1.5$  kcal mol<sup>-1</sup>. A calculation at the W2DK level of theory gave an enthalpy of 67.50 kcal mol<sup>-1</sup>.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

**C<sub>2</sub>CHBr** Enthalpy from review of Pedley.<sup>10</sup> An enthalpy of 74.1±3.1 kJ mol<sup>-1</sup> has been derived from a dissociative photoionization study of CH<sub>2</sub>BrCHBr<sub>2</sub> with a computed vinyl cation enthalpy.<sup>5</sup>

**CH<sub>2</sub>CH<sub>2</sub>Br**

An experimental study of the reaction Br + C<sub>2</sub>H<sub>4</sub> ↔ C<sub>2</sub>H<sub>4</sub>Br led to an enthalpy of reaction of 6.8±1.6 kcal mol<sup>-1</sup>.<sup>1</sup>

**CH<sub>3</sub>CHBr** A photobromination study leads to D(CH<sub>3</sub>CHBr-H) = 97.2±1 kcal mol<sup>-1</sup>.<sup>6</sup>

**CH<sub>3</sub>CH<sub>2</sub>Br**

Enthalpy obtained from a TPEPICO determination of the onset energy of the ethyl cation from the photodissociation of ethyl bromide, taking  $\Delta_f H_0^\circ(C_2H_5^+) = 915.5 \pm 1.3 \text{ kJ mol}^{-1}$ .<sup>2</sup> Previous enthalpy value,  $-61.5 \pm 1.0 \text{ kJ mol}^{-1}$ , was taken from review of the literature.<sup>3</sup> Entropy calculated by Kudchadker and Kudchadker.<sup>4</sup>

**C<sub>2</sub>Br<sub>2</sub>** An *ab initio* calculation at the W2DK level of theory.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

***trans*-CHBrCBr, *trans*-dibromovinyl radical**

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

**CH<sub>3</sub>CBr<sub>2</sub>** A photobromination study leads to  $D(CClF_2-H) = 94.9 \pm 1.2 \text{ kcal mol}^{-1}$ .<sup>7</sup>

**CH<sub>3</sub>CBr<sub>2</sub>H** Taken from a review of the literature.<sup>3</sup>

**CHBrCBr<sub>2</sub>, tribromoethene**

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

**CH<sub>2</sub>BrCH<sub>2</sub>Br**

Enthalpy from review of Pedley.<sup>10</sup>

**C<sub>2</sub>Br<sub>3</sub>** A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

**CH<sub>2</sub>BrCHBr<sub>2</sub>**

Enthalpy derived from a dissociative photoionization study of CH<sub>2</sub>BrCHBr<sub>2</sub> and a computed vinyl cation enthalpy.<sup>5</sup>

**CH<sub>3</sub>CBr<sub>3</sub>** Taken from a Thermodynamics Research Center review. Enthalpy estimated.<sup>4</sup>

**C<sub>2</sub>Br<sub>4</sub>, CHBr<sub>2</sub>CBr<sub>2</sub>, CBr<sub>3</sub>CHBr, C<sub>2</sub>Br<sub>5</sub>, C<sub>2</sub>Br<sub>6</sub>**

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.<sup>9</sup> Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

[Back to Table](#)

<b>IO</b>	The photodissociation dynamics of expansion-cooled IO was investigated, using velocity map ion imaging. This led to $D_0 = 54.9 (+0.2 -0.4) \text{ kcal mol}^{-1}$ and to the recommended enthalpy values. <sup>3</sup> Previous recommendation of the enthalpy, $\Delta_f H_{\theta}^o = 127.2 \pm 2.5 \text{ kJ mol}^{-1}$ , $\Delta_f H_{298}^o = 125.1 \pm 2.5 \text{ kJ mol}^{-1}$ , was from a CCSD(T) calculation of the dissociation energy, both directly and thorough a negative ion thermochemical cycle. <sup>10</sup> The NIST-JANAF thermochemical tables for iodine oxides recommends $\Delta_f H_{298}^o = 126 \pm 18 \text{ kJ mol}^{-1}$ and $\Delta_f H_{\theta}^o = 128 \pm 18 \text{ kJ mol}^{-1}$ , based on molecular beam studies. <sup>2</sup> The earlier spectroscopic studies are also discussed here. An equilibrium constant derived from the forward and reverse rate constants for $\text{IO} + \text{ClO} \leftrightarrow \text{I} + \text{OCIO}$ leads to an enthalpy at 298 K of about 28.6 kcal mol <sup>-1</sup> (using reference values from this table) and 27.5 kcal mol <sup>-1</sup> from the equilibrium $\text{Cl} + \text{IO} \leftrightarrow \text{I} + \text{ClO}$ . <sup>1</sup> Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $\text{I} + \text{O} \rightarrow \text{IO}$ , using Table reference values, leads to $\Delta_f H_{298}^o = 117.3 \text{ kJ mol}^{-1}$ . <sup>7</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^o = 128.0 \pm 6 \text{ kJ mol}^{-1}$ and $\Delta_f H_{\theta}^o = 130.1 \pm 6 \text{ kJ mol}^{-1}$ . <sup>5</sup> Entropy based on extensive calculations. <sup>6</sup>
<b>OIO</b>	The enthalpy value was from a determination of the threshold for the appearance of IO upon pulsed photolysis of OIO, indicating a bond strength of $D_0(\text{O}-\text{IO}) = 248.8 \pm 1 \text{ kJ mol}^{-1}$ . <sup>4</sup> The previous values of $\Delta_f H_{298}^o = 117.7 \pm 6 \text{ kJ mol}^{-1}$ and $\Delta_f H_{\theta}^o = 123.4 \pm 6 \text{ kJ mol}^{-1}$ were from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>5</sup> Molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory provided the entropy and, with this information, an enthalpy of $\Delta_f H_{298}^o = 75 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df energies coupled with isodesmic reactions. <sup>9</sup> A more recent computational study gives an enthalpy at 0 K of $113.9 \pm 10.3 \text{ kJ mol}^{-1}$ . <sup>8</sup> Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $2\text{IO} \rightarrow \text{OIO} + \text{I}$ leads to a 298 K enthalpy of $110.1 \text{ kJ mol}^{-1}$ . <sup>7</sup>
<b>IOO</b>	Enthalpy for the reaction $\text{HOOI} + \text{FOO} \rightarrow \text{HOOF} + \text{IOO}$ at the CCSD(T)/CBS(DTQ) level of theory, adjusted for the Table value for FOO, leads the cited enthalpy. <sup>5</sup> Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^o = 96 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df energies coupled with isodesmic reactions. <sup>9</sup>
<b>IO<sub>3</sub></b>	Enthalpy at 298 K of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $\text{OIO} + \text{IO}_3 \rightarrow \text{I}_2\text{O}_5$ . <sup>7</sup> Entropy and enthalpy difference from NIST-JANAF thermochemical tables for iodine oxides. <sup>2</sup> Previous enthalpy value of $242 \text{ kJ mol}^{-1}$ was estimated.

<b>IOI</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>5</sup> Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^o = 92.5 \pm 17$ kJ mol <sup>-1</sup> was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions. <sup>9</sup>
<b>IIO</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. Listed value is for the <sup>1</sup> A' state. $\Delta_f H_{298}^o = 234.3 \pm 6$ kJ mol <sup>-1</sup> for the <sup>3</sup> A <sub>2</sub> state. <sup>5</sup> Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^o = 134 \pm 17$ kJ mol <sup>-1</sup> was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions. <sup>9</sup>
<b>IOOI</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>5</sup> Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^o = 157$ kJ mol <sup>-1</sup> was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions. <sup>9</sup> Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for IO + IO → IOOI leads to a 298 K enthalpy of 179.9 kJ mol <sup>-1</sup> . <sup>7</sup>
<b>IIO<sub>2</sub></b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>5</sup> Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^o = 103$ kJ mol <sup>-1</sup> was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions. <sup>9</sup> Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for IO + IO → IIO <sub>2</sub> , using Table reference values, leads to a 298 K enthalpy of 157.9 kJ mol <sup>-1</sup> . <sup>7</sup>
<b>IOIO</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>5</sup> Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^o = 124$ kJ mol <sup>-1</sup> was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions. <sup>9</sup> Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for IO + IO → IOIO leads to a 298 K enthalpy of 141.3 kJ mol <sup>-1</sup> . <sup>7</sup>
<b>OIOO</b>	The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. <sup>5</sup> Molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory. Enthalpy derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions gives $\Delta_f H_{298}^o = 224$ kJ mol <sup>-1</sup> . <sup>9</sup>
<b>I<sub>2</sub>O<sub>3</sub></b>	Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for IO + OIO → I <sub>2</sub> O <sub>3</sub> . <sup>7</sup>
<b>I<sub>2</sub>O<sub>4</sub></b>	Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for 2OIO → I <sub>2</sub> O. <sup>7</sup>
<b>I<sub>2</sub>O<sub>5</sub></b>	Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for I <sub>2</sub> O <sub>4</sub> + O <sub>3</sub> → I <sub>2</sub> O <sub>5</sub> + O. <sup>7</sup>

**HOI**

Reaction enthalpies for a set of isogyric reactions were calculated using CR-CCSD(T) with single and double excitation and with second-order spin-free Douglas-Kroll-Hess Hamiltonian applied to account for the scalar relativistic effects. The listed values are from a recalculation using the present Table values, which are particularly different for IO and OH. The authors report:  $\Delta_f H_{298}^o = -69.0 \pm 3.7 \text{ kJ mol}^{-1}$ .<sup>6</sup> A computational study of the  $\text{OH} + \text{CH}_2\text{BrI} \rightarrow \text{HOI} + \text{CH}_2\text{Br}$  reaction at the DK-CCSD(T)/ANO-RCC-L(1)/MP2/ccpVTZ level of theory led to  $\Delta_f H_{298}^o = -62.9 \text{ kJ mol}^{-1}$ .<sup>5</sup> The previous values of  $\Delta_f H_{298}^o = -69.6 \pm 5.4 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^o = -64.9 \pm 5.4 \text{ kJ mol}^{-1}$  was based on the measured activation energy of the reaction  $\text{OH} + \text{CF}_3\text{I} \rightarrow \text{CF}_3 + \text{HOI}$  and G2(MP2) calculation indicating a negligible barrier for the reverse reaction.<sup>2</sup> Entropy based on extensive calculations.<sup>3</sup> Enthalpy values have also been calculated using the isogyric reaction  $\text{HOOH} + \text{IO} \rightarrow \text{HOO} + \text{HOI}$  with density functional theory (GP96PW91 level), leading to  $-58.6 \text{ kJ mol}^{-1}$  and  $-63.3 \text{ kJ mol}^{-1}$  at 0 and 298 K, employing reference enthalpies from this Table.<sup>1</sup> A calculation involving a pair of isodesmic reactions at the CCSD(T) level of theory in conjunction with the aug-cc-pVTZ-PP and aug-cc-pVQZ-PP basis sets led to  $\Delta_f H_{298}^o = -59.2 \pm 3.9 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^o = -54.5 \pm 3.9 \text{ kJ mol}^{-1}$ .<sup>4</sup>

**HIO**

Enthalpy difference calculated  $\text{HOI} \rightarrow \text{HIO}$  with density functional theory (GP96PW91 level).<sup>1</sup>

**HOIO**

Enthalpy difference calculated  $\text{HOOI} \rightarrow \text{HOIO}$  with density functional theory (GP96PW91 level),  $\Delta_f H_0^o = -11.0 \text{ kJ mol}^{-1}$ .<sup>1</sup>

**HOOI**

Enthalpy values calculated using the isogyric reaction  $\text{HOOH} + \text{IO} \rightarrow \text{HO} + \text{HOOI}$  with density functional theory (GP96PW91 level), employing reference enthalpies from this Table.<sup>1</sup>

<b>INO</b>	Thermodynamic parameters from a third-law analysis of the equilibrium reaction I + NO (+He) $\leftrightarrow$ INO (+He). <sup>4</sup> Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for I + NO $\rightarrow$ INO, using Table reference values, leads to a 298 K enthalpy of 134.2 kJ mol <sup>-1</sup> . <sup>1</sup>
<b>INO<sub>2</sub></b>	Thermodynamic parameters from a third-law analysis of the equilibrium reaction I + NO <sub>2</sub> (+He) $\leftrightarrow$ INO <sub>2</sub> (+He). <sup>4</sup>
<b>IOONO</b>	Derived from CCSD(T) single-point calculations at B3LYP geometries for the interconversion of the two isomers. <sup>3</sup> The dissociation energy for IOONO <sub>2</sub> was also calculated to be 131.4 kJ mol <sup>-1</sup> , leading to an enthalpy at 298K for that isomer of 24.8 kJ mol <sup>-1</sup> , whereas a value of 37.5 kJ mol <sup>-1</sup> has been selected for this Table.
<b>IONO<sub>2</sub></b>	The enthalpy values were derived from the average of the IO – NO <sub>2</sub> bond dissociation energies calculated by Kaltsoyannis and Plane <sup>1</sup> and by Marshall. <sup>2</sup> See Table 3-1, note 32 for more details. The selected entropy value is also discussed in that note.

[Back to Table](#)

<b>CHI</b>	Enthalpy obtained using the computed enthalpy of a reaction of the type: CH <sub>2</sub> ( <sup>1</sup> A <sub>1</sub> ) + CH <sub>3</sub> X + CH <sub>3</sub> Y $\rightarrow$ CXY( <sup>1</sup> A <sub>1</sub> ) + 2CH <sub>4</sub> at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. <sup>8</sup>
<b>CH<sub>2</sub>I</b>	Enthalpy value from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. <sup>7</sup> A computational study of the OH + CH <sub>3</sub> I $\rightarrow$ H <sub>2</sub> O + CH <sub>2</sub> I reaction at the DK-CCSD(T)/ANO-RCC-L(1)//MP2/ccpVTZ level of theory led to $\Delta_fH_{298}^o = 215.9$ kJ mol <sup>-1</sup> and $\Delta_fH_0^o = 220.2$ kJ mol <sup>-1</sup> . <sup>6</sup> These values provided the enthalpy difference utilized. A subsequent study on the reaction OH + CH <sub>2</sub> IBr $\rightarrow$ HOBr + CH <sub>2</sub> I led to $\Delta_fH_{298}^o = 218.4$ kJ mol <sup>-1</sup> and $\Delta_fH_0^o = 223.3$ kJ mol <sup>-1</sup> . <sup>12</sup> Previous enthalpy value of $228.0 \pm 2.8$ kJ mol <sup>-1</sup> from <i>ab initio</i> calculations used to determine the entropies of the reactants and the transition state for Br + CH <sub>3</sub> I $\rightarrow$ HBr + CH <sub>2</sub> I. Arrhenius parameters were then calculated by transition state theory. The kinetics of the reverse reactions were measured in a flow system. The enthalpy value was obtained from a second-law analysis. <sup>9</sup>
<b>CH<sub>3</sub>I</b>	Calculated from the dissociation of energy-selected CH <sub>3</sub> I <sup>+</sup> and its adiabatic ionization energy. <sup>10</sup> Enthalpy from rotating combustion calorimetry is $14.4 \pm 1.4$ kJ mol <sup>-1</sup> . <sup>2</sup> A review of the literature gave $\Delta_fH_{298}^o = 13.8 \pm 1.2$ kJ mol <sup>-1</sup> and the enthalpy difference; the entropy is from ideal gas thermodynamic properties. <sup>3</sup>
<b>Cl<sub>2</sub></b>	Enthalpy obtained using the computed enthalpy of a reaction of the type: CH <sub>2</sub> ( <sup>1</sup> A <sub>1</sub> ) + CH <sub>3</sub> X + CH <sub>3</sub> Y $\rightarrow$ CXY( <sup>1</sup> A <sub>1</sub> ) + 2CH <sub>4</sub> at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. <sup>8</sup>
<b>CHI<sub>2</sub></b>	Enthalpy value from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. <sup>7</sup> A computational study of the OH + CH <sub>3</sub> I $\rightarrow$ HOI + CHI <sub>2</sub> reaction at the CCSD(T)/ANO-RCC-Large//MP2/ccpVTZ level of theory led to $\Delta_fH_{298}^o = 309.2$ kJ mol <sup>-1</sup> and $\Delta_fH_0^o = 298.9$ kJ mol <sup>-1</sup> . <sup>11</sup> These values provided the

enthalpy difference utilized. A computational study of the  $\text{OH} + \text{CH}_2\text{I}_2 \rightarrow \text{H}_2\text{O} + \text{CHI}_2$  reaction at the DK-CCSD(T)/ANO-RCC-L(1)//MP2/ccpVTZ level of theory led to  $\Delta_f H_{298}^o = 298.7 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^o = 303.5 \text{ kJ mol}^{-1}$ .<sup>6</sup> Previous enthalpy value of  $314.4 \pm 3.3 \text{ kJ mol}^{-1}$  from *ab initio* calculations used to determine the entropies of the reactants and the transition state for  $\text{Br} + \text{CH}_2\text{I}_2 \rightarrow \text{HBr} + \text{CHI}_2$ . Arrhenius parameters were then calculated by transition state theory. The kinetics of the reverse reactions were estimated. The enthalpy value was obtained from a second-law analysis.<sup>9</sup>

<b>CH<sub>2</sub>I<sub>2</sub></b>	Enthalpy taken from a dissociative photoionization study of a series of dihalomethanes, normalized using the experimental enthalpy of dichloromethane. <sup>5</sup> The reported value has been adjusted by $+0.4 \text{ kJ mol}^{-1}$ to agree with the present enthalpy for CH <sub>2</sub> Cl <sub>2</sub> . Previous value of $119.5 \pm 2.2 \text{ kJ mol}^{-1}$ from rotating combustion calorimetry. <sup>2</sup> <i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl iodide, resulted in an enthalpy value of $108.1 \pm 6 \text{ kJ mol}^{-1}$ . <sup>7</sup> A review of the literature gave $\Delta_f H_{298}^o = 117.6 \pm 4.2 \text{ kJ mol}^{-1}$ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties. <sup>4</sup> In a more recent study, involving a TPEPICO determination of the heat of formation of 1,2-C <sub>2</sub> H <sub>4</sub> I <sub>2</sub> , an analysis of the <i>ab initio</i> isodesmic reactions energies of four reactions led to a recommendation that the enthalpy values be reduced to $\Delta_f H_0^o = 123.1 \pm 2.0 \text{ kJ mol}^{-1}$ and $\Delta_f H_{298}^o = 113.5 \pm 2.0 \text{ kJ mol}^{-1}$ . <sup>1</sup>
<b>CHI<sub>3</sub></b>	<i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl iodide. <sup>7</sup> Previous enthalpy value of $251.1 \pm 1.4 \text{ kJ mol}^{-1}$ from rotating combustion calorimetry. <sup>2</sup> A review of the literature gave $\Delta_f H_{298}^o = 210.9 \pm 4.2 \text{ kJ mol}^{-1}$ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties. <sup>3</sup>
<b>CI<sub>3</sub></b>	Enthalpy value from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. <sup>7</sup> A computational study of the OH + CH <sub>3</sub> I → H <sub>2</sub> O + CI <sub>3</sub> reaction at the CCSD(T)/ANO-RCC-Large//MP2/ccpVTZ level of theory led to $\Delta_f H_{298}^o = 387.4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^o = 384.4 \text{ kJ mol}^{-1}$ . <sup>11</sup> These values provided the enthalpy difference utilized. Previous enthalpy value of $424.9 \pm 2.8 \text{ kJ mol}^{-1}$ from <i>ab initio</i> calculations used to determine the entropies of the reactants and the transition state for Br + CH <sub>2</sub> I <sub>2</sub> → HBr + CHI <sub>2</sub> . Arrhenius parameters were then calculated by transition state theory. The kinetics of the reverse reactions were estimated. The enthalpy value was obtained from a second-law analysis. <sup>9</sup> The uncertainty in the <i>ab initio</i> was suggested to be $\pm 9 \text{ kJ mol}^{-1}$ . We have expanded that considerably due to these obvious disagreements.
<b>CI<sub>4</sub></b>	<i>Ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl iodide. <sup>7</sup> Previous enthalpy value of $474 \pm 13 \text{ kJ mol}^{-1}$ from rotating combustion calorimetry. <sup>2</sup> A review of the literature estimated $\Delta_f H_{298}^o = 268 \pm 4.2 \text{ kJ mol}^{-1}$ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties. <sup>4</sup> The uncertainty in the <i>ab initio</i> was suggested to be $\pm 12 \text{ kJ mol}^{-1}$ . We have expanded that considerably due to these obvious disagreements.

**Note 73:** *Compounds containing S, H and O*

[Back to Table](#)

<b>HSO</b>	An enthalpy at 0 K determined to be $-0.9 \pm 0.7 \text{ kcal mol}^{-1}$ ( $-3.8 \pm 2.9 \text{ kJ mol}^{-1}$ ) from crossed beam reactive scattering of O + H <sub>2</sub> S. <sup>2</sup> This was the value recommended in the previous Table. In a more recent study, the authors suggested that the lower bound to the uncertainty could be as much as $-3 \text{ kcal mol}^{-1}$ , but confirmed the upper bound as $0.7 \text{ kcal mol}^{-1}$ . <sup>3</sup> A number of computational studies have converged on the significantly lower value presently recommended, which is taken from a study where the atomization energy was calculated by CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. <sup>7</sup> This value was chosen for consistency with the other HxOySz species from the same work included in the table. In a more recent study, at the CCSDT(Q)/cc-pV(T+d)Z level, led to a value of $\Delta_f H_{298}^{\circ} = -22.6 \pm 2.3 \text{ kJ mol}^{-1}$ , in close agreement, and to the entropy value cited. <sup>8</sup>
<b>HOS</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. <sup>7</sup> In a more recent study, at the CCSDT(Q)/cc-pV(T+d)Z level, led to a value of $\Delta_f H_{298}^{\circ} = -5.3 \pm 2.3 \text{ kJ mol}^{-1}$ , in close agreement, and to the entropy value cited. <sup>8</sup>
<b>HSO<sub>2</sub></b>	Enthalpy obtained with DFT calculations on dissociation, atomization, and isodesmic reactions. <sup>5</sup> Value supported by a calculation of the H + SO <sub>2</sub> dissociation asymptote. <sup>1</sup> The latter study shows that HOSO is the more stable configuration, with HSO(O) as a local minimum.
<b>HOSO</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. <sup>7</sup> Lowest energy configuration is the <i>cis</i> isomer. Values for the <i>trans</i> isomer are $\Delta_f H_{298}^{\circ} = -56.2 \pm 1 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^{\circ} = -55.1 \pm 1 \text{ kcal mol}^{-1}$ . Another CCSD(T) calculation to the CBS limit, with additional corrections, including correlation through the the CBSDT(Q) level, resulted in values for these isomers (identified as the <i>syn</i> and <i>anti</i> isomers) of $\Delta_f H_0^{\circ} = -58.0 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^{\circ} = -55.7 \text{ kcal mol}^{-1}$ , respectively. <sup>9</sup>
<b>HSOO</b>	Enthalpy for the reaction HOOSH + FOO → HOOF + HSOO at the CCSD(T)/CBS(Q,5) level of theory is 18.00 kcal mol <sup>-1</sup> . Adjusted for the Table reference values, this gives the cited enthalpy of formation. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer. Values for the <i>cis</i> isomer are $\Delta_f H_{298}^{\circ} = 29.9 \pm 1 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^{\circ} = 31.3 \pm 1 \text{ kcal mol}^{-1}$ and for the <i>trans</i> isomer $\Delta_f H_{298}^{\circ} = 29.8 \pm 1 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^{\circ} = 31.2 \pm 1 \text{ kcal mol}^{-1}$ .
<b>HOSH</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. $\Delta_f H_0^{\circ} = -26.5 \pm 1 \text{ kcal mol}^{-1}$ . <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer. Values for the <i>trans</i> isomer are $\Delta_f H_{298}^{\circ} = -24.3 \pm 1 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^{\circ} = -22.7 \pm 1 \text{ kcal mol}^{-1}$ and for the <i>cis</i> isomer $\Delta_f H_{298}^{\circ} = -22.6 \pm 1 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^{\circ} = -21.0 \pm 1 \text{ kcal mol}^{-1}$ .
<b>HOOS</b>	Enthalpy for the reaction HOOSH + FOO → HOOF + HOOS at the CCSD(T)/CBS(Q,5) level of theory is 5.14 kcal mol <sup>-1</sup> . Adjusted for the Table reference values, this gives the cited enthalpy of formation, $\Delta_f H_0^{\circ} = 15.3 \pm 1.5 \text{ kcal mol}^{-1}$ . <sup>7</sup>
<b>HOOSH</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer.
<b>HOSOH</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer.
<b>HOSO<sub>2</sub></b>	Thermodynamic parameters calculated at the CCSDT(Q)/cc-pV(T+d)Z level of theory. <sup>8</sup> A third-law analysis of equilibrium data for the reaction OH + SO <sub>2</sub> ↔ HOSO <sub>2</sub> (extrapolated from data over the temperature range 523 to 603 K) led to $\Delta_f H_{298}^{\circ} = 373 \pm 6 \text{ kJ mol}^{-1}$ , in good agreement with the computed value. <sup>4</sup>
<b>H<sub>2</sub>SO<sub>4</sub></b>	Taken from review of Dorofeeva et al. <sup>6</sup>

<b>HOSS</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. <sup>7</sup> Lowest energy configuration is the <i>cis</i> isomer. Values for the <i>trans</i> isomer are $\Delta_f H_{298}^0 = -13.6 \pm 1$ kcal mol <sup>-1</sup> and $\Delta_f H_0^\circ = -12.7 \pm 1$ kcal mol <sup>-1</sup> .
<b>HSSO</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer. Values for the <i>cis</i> isomer are $\Delta_f H_{298}^0 = -9.1 \pm 1$ kcal mol <sup>-1</sup> and $\Delta_f H_0^\circ = -7.8 \pm 1$ kcal mol <sup>-1</sup> and for the <i>trans</i> isomer $\Delta_f H_{298}^0 = -8.7 \pm 1$ kcal mol <sup>-1</sup> and $\Delta_f H_0^\circ = -7.8 \pm 1$ kcal mol <sup>-1</sup> .
<b>HSOS</b>	Enthalpy for the reaction $\text{HSOSH} + \text{FOO} \rightarrow \text{HOOF} + \text{HSOS}$ at the CCSD(T)/CBS(Q,5) level of theory is 8.81 kcal mol <sup>-1</sup> . Adjusted for the Table reference values, this gives the cited enthalpy of formation. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer. Values for the <i>cis</i> isomer are $\Delta_f H_{298}^0 = 27.5 \pm 1$ kcal mol <sup>-1</sup> and $\Delta_f H_0^\circ = 28.9 \pm 1$ kcal mol <sup>-1</sup> and for the <i>trans</i> isomer $\Delta_f H_{298}^0 = 28.1 \pm 1$ kcal mol <sup>-1</sup> and $\Delta_f H_0^\circ = 28.9 \pm 1$ kcal mol <sup>-1</sup> .
<b>HOSSH</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer.
<b>HSOSH</b>	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. <sup>7</sup> Lowest energy configuration is the <i>syn</i> isomer.

[Back to Table](#)

**CS** Taken from review of Gurvich et al.<sup>5</sup> The JANAF tables give  $\Delta_f H_0^\circ = 277.1 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = 280.3 \text{ kJ mol}^{-1}$ , and  $S^\circ = 210.554 \text{ J mol}^{-1}$ .

**CS<sub>2</sub>** Taken from review of Gurvich et al.<sup>5</sup> The JANAF tables give  $\Delta_f H_0^\circ = 116.1 \text{ kJ mol}^{-1}$ ,  $\Delta_f H_{298}^\circ = 116.9 \text{ kJ mol}^{-1}$ , and  $S^\circ = 237.977 \text{ J mol}^{-1}$ .

**HCS** Enthalpy  $\Delta_f H_0^\circ = 71.7 \pm 2.0 \text{ kcal mol}^{-1}$  obtained from a photoionization study of CH<sub>2</sub>S and CHS, obtained by sequential abstraction from CH<sub>3</sub>SH.<sup>10</sup> 298 K value from Berkowitz et al.<sup>1</sup>

**CH<sub>2</sub>S** Enthalpy  $\Delta_f H_0^\circ = 28.3 \pm 2.0 \text{ kcal mol}^{-1}$  obtained from a photoionization study of CH<sub>2</sub>S and CHS, obtained by sequential abstraction from CH<sub>3</sub>SH.<sup>10</sup> Integrated heat capacity from Berkowitz et al.<sup>1</sup>

**CH<sub>3</sub>S** Second- and third-law analysis were utilized to obtain an enthalpy of reaction of  $-0.14 \pm 0.28 \text{ kcal mol}^{-1}$  for the reaction Br + CH<sub>3</sub>SH  $\leftrightarrow$  HBr + CH<sub>3</sub>S.<sup>7</sup> Enthalpy calculated at the CCSD(T)/CBS level of theory is 29.7 kcal mol<sup>-1</sup>.<sup>9</sup> DFT calculations support an enthalpy value of  $29.78 \pm 0.44 \text{ kcal mol}^{-1}$ .<sup>3</sup>

<b>CH<sub>2</sub>SH</b>	A photoionization study <sup>10</sup> leads to a recommended value for H-CH <sub>2</sub> SH of 93.9±2.0 kcal mol <sup>-1</sup> . <sup>1</sup> The enthalpy is from this and the present values for H and CH <sub>3</sub> SH. Enthalpy values calculated at the CCSDT(Q)/cc-pV(T+d)Z level of theory give $\Delta_fH_0^\circ = 142.6 \text{ kJ mol}^{-1}$ and $\Delta_fH_{298}^\circ = 143.4 \text{ kJ mol}^{-1}$ . <sup>6</sup> The entropy value is also from this reference.
<b>CH<sub>3</sub>SH</b>	Enthalpy from Pedley <sup>8</sup> entropy from Frenkel et al. <sup>4</sup> Enthalpy calculated at the CCSD(T)/CBS level of theory is -5.31 kcal mol <sup>-1</sup> . <sup>9</sup>

[Back to Table](#)

<b>CS<sub>2</sub>OH</b>	The temperature dependence of the equilibrium constant for the reaction OH + CS <sub>2</sub> $\leftrightarrow$ CS <sub>2</sub> OH resulted in a heat of reaction of -10.9±1.0 kcal mol <sup>-1</sup> and an entropy change of -24.0±4.4 cal K <sup>-1</sup> mol <sup>-1</sup> . <sup>6</sup>
<b>CH<sub>2</sub>SO</b>	Thermodynamic parameters calculated at the CCSDT(Q)/cc-pV(T+d)Z level of theory. <sup>7</sup> An enthalpy value of $\Delta_fH_{298}^\circ = -30 \text{ kJ mol}^{-1}$ was derived from CBS-QB3 calculations on 10 reactions (one isodesmic). <sup>9</sup>
<b>CH<sub>2</sub>S(O)O</b>	Enthalpy derived from B3PW91 and OBS-QB3 calculations on 3 reactions (one isodesmic). <sup>11</sup>
<b>CH<sub>3</sub>SO</b>	Derived from an reaction enthalpy of -22.88 kcal mol <sup>-1</sup> for the isodesmic reaction CH <sub>3</sub> S + SO <sub>3</sub> $\rightarrow$ CH <sub>3</sub> SO + SO <sub>2</sub> calculated at the CCSD(T) level extrapolated to the CBS limit. <sup>8</sup>
<b>CH<sub>3</sub>S(O)O</b>	Enthalpies of formation determined using five isodesmic reactions, with structures, vibrational frequencies, and rotational energies calculated at the B3LYP/6-311G(2p,d) level of theory, while the enthalpies were calculated at the CBS-QB3 level. <sup>4</sup> Heat of atomization, dissociation, and three isodesmic reactions calculated at the G2(MP2) level of theory gave $\Delta_fH_{298}^\circ = -211 \text{ kJ mol}^{-1}$ , used in the previous Table. <sup>3</sup> Enthalpy calculated at the CCSD(T)/CBS level of theory is -52.2 kcal mol <sup>-1</sup> . <sup>8</sup> A DFT estimate gives -56.3 kcal mol <sup>-1</sup> . <sup>2</sup>
<b>CH<sub>3</sub>OSO</b>	Heat of atomization, dissociation, and two isodesmic reactions calculated at the G2(MP2) level of theory to yield the enthalpy of formation. <sup>3</sup>

**CH<sub>3</sub>SOO** The equilibrium constant for the reaction CH<sub>3</sub>S + O<sub>2</sub> ↔ CH<sub>3</sub>SOO was measured between 216 to 258 K and resulted in a bond strength of 11.7±0.9 kcal mol<sup>-1</sup>.<sup>10</sup>

**CH<sub>2</sub>S(O)OH and CH<sub>3</sub>S(O)OH**

Enthalpies of formation determined using five isodesmic reactions, with structures, vibrational frequencies, and rotational energies calculated at the B3LYP/6-311G(2p,d) level of theory, while the enthalpies were calculated at the CBS-QB3 level.<sup>4</sup>

**OCS** Taken from review of Gurvich et al.<sup>5</sup> The JANAF Tables give Δ<sub>f</sub>H<sub>0</sub><sup>o</sup> = -138.5 kJ mol<sup>-1</sup>, Δ<sub>f</sub>H<sub>298</sub><sup>o</sup> = -138.4 kJ mol<sup>-1</sup>, and S<sup>o</sup> = 231.581 J mol<sup>-1</sup>.

## **Note 82: Compounds containing Na**

[Back to Table](#)

### **Na**

CODATA Key Value.<sup>2</sup> The Lamoreaux and Hildenbrand review gives  $\Delta_f H_{298}^\circ = 107.1 \pm 0.4 \text{ kJ mol}^{-1}$  and  $S^\circ = 153.57 \text{ J mol}^{-1}$ .<sup>4</sup>

### **Na<sub>2</sub>**

Enthalpy and entropy values from the JANAF tables.<sup>1</sup>

### **NaH**

Enthalpy and entropy values from the JANAF tables.<sup>1</sup>

### **NaF**

Enthalpy and entropy values from the JANAF tables.<sup>1</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^\circ = -291.6 \pm 4 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = -290.0 \pm 4 \text{ kJ mol}^{-1}$ .<sup>6</sup>

### **NaCl**

Enthalpy and entropy values from the JANAF tables.<sup>1</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^\circ = -180.3 \pm 4 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = -178.7 \pm 4 \text{ kJ mol}^{-1}$ .<sup>6</sup>

### **NaBr**

Enthalpy and entropy values from the JANAF tables.<sup>1</sup>

### **NaOH**

From an extensive evaluation from the Thermocenter of the RAS.<sup>3</sup> The JANAF Tables give  $\Delta_f H_{298}^\circ = -198 \pm 12 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = -194 \pm 12 \text{ kJ mol}^{-1}$ , and  $S^\circ = 228.44 \text{ J mol}^{-1}$ .<sup>1</sup> A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to  $\Delta_f H_{298}^\circ = -187.0 \pm 4 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = -184.1 \pm 4 \text{ kJ mol}^{-1}$ .<sup>6</sup>

### **NaO**

The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.<sup>6</sup> Cited values are for the  $^2\Pi$  state. For the  $^2\Sigma^+$  state  $\Delta_f H_{298}^\circ = 113.8 \pm 4 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = 115.5 \pm 4 \text{ kJ mol}^{-1}$ . The JANAF values are  $\Delta_f H_{298}^\circ = 84 \pm 40 \text{ kJ mol}^{-1}$  and  $\Delta_f H_0^\circ = 85 \pm 40 \text{ kJ mol}^{-1}$ , and the cited entropy.<sup>1</sup> The Pedley and Marshall review

gives  $\Delta_f H_{298}^o = 100 \pm 17$  kJ mol<sup>-1</sup>.<sup>5</sup> The Lamoreaux and Hildenbrand review gives  $\Delta_f H_{298}^o = 104.6 \pm 4.2$  kJ mol<sup>-1</sup> and  $S^o = 228.48$  J mol<sup>-1</sup>.<sup>4</sup>

**Note 84:** Compounds containing Hg and H or O

[Back to Table](#)

<b>Hg<sup>0</sup></b>	CODATA key values, <sup>2</sup> with the 0 K value calculated in JANAF. <sup>1</sup> The NBS Tables give $\Delta_fH^0(298 \text{ K}) = 61.32 \text{ kJ mol}^{-1}$ and $S^0 = 179.03 \text{ J mol}^{-1} \text{ K}^{-1}$ . <sup>11</sup> The review of Hepler and Olofsson accept the NBS value, but also discuss some more recent vapor pressure measurements. <sup>6</sup>
<b>HgH</b>	Chosen values from the JANAF Table, <sup>1</sup> based on results reported by Herzberg. <sup>7</sup> Also selected by Hepler and Olofsson. <sup>6</sup> The NBS Tables give $\Delta_fH^0(298 \text{ K}) = 239.32 \text{ kJ mol}^{-1}$ and $S^0 = 219.49 \text{ J mol}^{-1} \text{ K}^{-1}$ . <sup>11</sup> A calculation using NESC/CCSD(T) in combination with triple-zeta basis sets, gave BDE = 38.5 kJ mol <sup>-1</sup> , which leads to $\Delta_fH^0(0 \text{ K}) = 238.76 \text{ kJ mol}^{-1}$ . <sup>3</sup>
<b>HgH<sub>2</sub></b>	The cited enthalpy values are an average of those calculated for the atomization energy and for the bond-dissociation reaction, $\text{HgH}_2 \rightarrow \text{HgH} + \text{H}$ , both done at the NESC/B3LYP level of theory. <sup>3</sup>
<b>HgO</b>	The selected enthalpy of formation is derived from computational determinations of the bond dissociation energy. Dissociation from both the ${}^1\Sigma^+$ (to $\text{Hg}{}^1\text{S}$ and $\text{O}{}^1\text{D}$ ) and ${}^3\Pi$ (to $\text{Hg}{}^1\text{S}$ and $\text{O}{}^3\text{P}$ ) states of HgO have been reported, with some disagreement about which is the ground state. From a relativistically-corrected MP4/CCSD(T) calculation, $D_0 = 9.2 \text{ kJ mol}^{-1}$ from a triplet ground state by Filatov and Cremer. <sup>4</sup> A subsequent study from the same group, adding the normalized elimination of the small component technique to improve the treatment of scalar relativistic effects, found the ${}^3\Pi$ state 5.4 kJ mol <sup>-1</sup> lower than the ${}^1\Sigma^+$ state, and also calculated BDEs of 16.1 kJ mol <sup>-1</sup> along the triplet surface and 202.9 kJ mol <sup>-1</sup> along the singlet surface, both adjusted to 298 K. <sup>3</sup> At 0 K, the calculated triplet BDE was 14.6 kJ mol <sup>-1</sup> . In contrast, a MRCI + Q/CBS level calculation by Peterson et al. <sup>8</sup> found a singlet ground state and computed a BDE of 203.3 kJ mol <sup>-1</sup> at 0 K. This result is in agreement with earlier calculations from the same laboratory which resulted in a BDE to ground-state atoms of 17 and 19.1 kJ mol <sup>-1</sup> . <sup>9,10</sup>

There has been an experimental determination of the dissociation energy of HgO by using high-temperature mass spectrometry.<sup>5</sup> In strong disagreement with the computational studies, a value of  $222 \pm 33 \text{ kJ mol}^{-1}$  was determined. Filatov and Cremer<sup>4</sup> have made a compelling case that the species detected in the mass spectrometer being a dimer, either or both  $\text{HgO}_2\text{Hg}$  and  $\text{OHg}_2\text{O}$ . There is clearly a great need for additional experimental work on HgO, but at this point, we accept the theoretical argument.

[Back to Table](#)

**HgF, HgCl, HgBr, HgI, HgF<sub>2</sub>, HgCl<sub>2</sub>, HgBr<sub>2</sub>, HgI<sub>2</sub>**

At this time, we accept the JANAF values.<sup>3</sup> More recent experimental and computational results scatter around these values, with no clear pattern. These are discussed below.

**HgF**

The JANAF enthalpy value has a stated uncertainty of  $\pm 50 \text{ kJ mol}^{-1}$ . We have reduced this to  $\pm 20 \text{ kJ mol}^{-1}$  in light of the additional results discussed below. The JANAF enthalpy value leads to a BDE of  $134 \pm 20 \text{ kJ mol}^{-1}$  at 0 K. A MP4/CCSD(T) calculation, including a normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of  $129 \text{ kJ mol}^{-1}$ ,<sup>4</sup> while another CCSD(T) study led to values of 137 and  $115 \text{ kJ mol}^{-1}$  with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.<sup>6</sup>

**HgCl**

The JANAF enthalpy value leads to a BDE of  $102 \pm 10 \text{ kJ mol}^{-1}$  at 0 K. A reanalysis of the spectral data suggested a value of  $\sim 106 \text{ kJ mol}^{-1}$ .<sup>9</sup> A more recent spectral study led to an upper limit on the BDE of  $98 \text{ kJ mol}^{-1}$ ,<sup>8</sup> although an analysis of these data by using empirical potential energy functions led to BDE =  $107 \text{ kJ mol}^{-1}$ .<sup>2</sup> Computational results tend to be lower: A CCSD(T)/CBS with relativistic pseudopotentials, corrected for spin-orbit coupling, gave a BDE of  $96 \text{ kJ mol}^{-1}$ ,<sup>7</sup> whereas a MP4/CCSD(T) calculation, including a normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of  $89.5 \text{ kJ mol}^{-1}$ .<sup>4</sup> Another CCSD(T) study led to values of 94 and  $78 \text{ kJ mol}^{-1}$  with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.<sup>6</sup>

**HgBr**

The JANAF enthalpy value has a stated uncertainty of  $\pm 38 \text{ kJ mol}^{-1}$ . We have reduced this to  $\pm 10 \text{ kJ mol}^{-1}$  in light of the additional results discussed below. The JANAF enthalpy value leads to a BDE of  $67 \pm 10 \text{ kJ mol}^{-1}$  at 0 K. A reanalysis of the spectral data suggested a value

of  $\sim 72$  kJ mol $^{-1}$ .<sup>9</sup> A more recent spectral study led to a BDE of 66.1 kJ mol $^{-1}$ ,<sup>8</sup> although an analysis of these data by using empirical potential energy functions led to BDE = 61.75 kJ mol $^{-1}$ .<sup>2</sup> A CCSD(T)/CBS with relativistic pseudopotentials, corrected for spin-orbit coupling, gave a BDE of 68 kJ mol $^{-1}$ ,<sup>7</sup> whereas a MP4/CCSD(T) calculation, including a normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of 60 kJ mol $^{-1}$ .<sup>4</sup> Another CCSD(T) study led to values of 21 and 59 kJ mol $^{-1}$  with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.<sup>6</sup> A slightly different BDE of 66.3 kJ mol $^{-1}$  was used in the analysis of the equilibrium constant data in Table 3-1, Note 33.

<b>HgI</b>	The JANAF enthalpy value leads to a BDE of $32.9 \pm 5$ kJ mol $^{-1}$ at 0 K. A reanalysis of the spectral data suggested a value of 37.3 kJ mol $^{-1}$ . <sup>9</sup> A more recent spectral study led to a BDE of 33.5 kJ mol $^{-1}$ , <sup>8</sup> although an analysis of these data by using empirical potential energy functions led to BDE = 37.3 kJ mol $^{-1}$ . <sup>2</sup> A CCSD(T)/CBS calculation with relativistic pseudopotentials, corrected for spin-orbit coupling, <sup>7</sup> gave a BDE of 36 kJ mol $^{-1}$ whereas a MP4/CCSD(T) calculation, including the normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of 46 kJ mol $^{-1}$ . <sup>4</sup> Another CCSD(T) study led to values of 15 and 38.5 kJ mol $^{-1}$ with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively. <sup>6</sup>
<b>HgF<sub>2</sub></b>	In this case, the values listed in the JANAF Table are estimated. Enthalpy values have been calculated for the atomization energy and for the bond-dissociation reaction, $\text{HgF}_2 \rightarrow \text{HgF} + \text{F}$ at the NESC/B3LYP level of theory, leading to average values of $\Delta_f H^0(298 \text{ K}) = -288$ kJ mol $^{-1}$ and $\Delta_f H^0(0 \text{ K}) = -296$ kJ mol $^{-1}$ . <sup>4</sup> A CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = -302$ and $-285$ kJ mol $^{-1}$ with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively. <sup>6</sup>
<b>HgCl<sub>2</sub></b>	The values listed in the JANAF Table are based on a third-law analysis. A CCSD(T) calculation utilizing small-core relativistic effective core potentials for the reaction $\text{Hg} + \text{Cl}_2 \rightarrow \text{HgCl}_2$ led to $\Delta_f H^0(0 \text{ K}) = -139$ kJ mol $^{-1}$ . <sup>1</sup> Another CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = -134$ and $-122$ kJ mol $^{-1}$ with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively. <sup>6</sup> A third CCSD(T) study, with the ECP60MDF relativistic core potential and B3LYP/aVTZ structures gave $-135$ kJ mol $^{-1}$ . <sup>5</sup>
<b>HgBr<sub>2</sub></b>	The values listed in the JANAF Table are based on a third-law analysis. A CCSD(T) calculation utilizing small-core relativistic effective core potentials for the reaction $\text{Hg} + \text{Br}_2 \rightarrow \text{HgBr}_2$ led to $\Delta_f H^0(0 \text{ K}) = -67$ kJ mol $^{-1}$ . <sup>1</sup> Another CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = -42$ and $-34$ kJ mol $^{-1}$ with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively. <sup>6</sup> A third CCSD(T) study, with the ECP60MDF relativistic core potential and B3LYP/aVTZ structures gave $\Delta_f H^0(0 \text{ K}) = -81$ kJ mol $^{-1}$ . <sup>5</sup>
<b>HgI<sub>2</sub></b>	The values listed in the JANAF Table are based on a third-law analysis. A calculated enthalpy for the reaction $\text{HgI}_2 \rightarrow \text{Hg} + \text{I}_2$ at the CCSD(T)/CBS limit with corrections for core-valence correlation, spin-orbit coupling, Lamb shift, and scalar relativity leads to the value $\Delta_f H^0(0 \text{ K}) = -16$ kJ mol $^{-1}$ . <sup>7</sup> Another CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = 9.6$ and $20$ kJ mol $^{-1}$ with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively. <sup>6</sup>

[Back to Table](#)

Bond energies obtained at the CCSD(T) level of theory with the ECP60MDF relativistic core potential and B3LYP/aVTZ structures. Results at the B3LP and CCSD levels also reported.<sup>1</sup> The same set of calculation led to  $\Delta_f\text{H}^0(0 \text{ K}) = -135$  and  $-81 \text{ kJ mol}^{-1}$  for  $\text{HgCl}_2$  and  $\text{HgBr}_2$ , respectively.
